I'm just curious, but if that noise is a squelch tail (???), doing something
with antennas isn't going to
stop it. Also, is the 139-141 MHZ area a police band in Canada?

Doc,

Find your county's radio shop and make friends with the radio tech (if your county does its own
radio work). You might be able to get hold of a ball mount there. Around here, there's no shortage of commercial grade ball mounts (used)--I see 'em at the hamfests all the time.

As to the coil sizes, what I found was that when you get into super hi Q, large diameter coils,
they seem to be difficult to keep in resonance. They are just SUPER sensitive to their surroundings,
and, as you move along, they will just die on ya, at the least change in the status quo. A friend and I spent an afternoon trying to resonate an 8" dia Bugcatcher on his truck. Sure, we could get it down to 1:5, but when you moved out of the yard, it was off again. Set it up the road at the church yard, or the nearby open field, same thing. But when you moved, it was off again. That's when we
went with a 3" Texas Twister that gave excellent performance and was not so persnickety about
everything it passed.

Hi
The MFJ-202B noise bridge has a switch labeled EXP/NOR. I can use the bridge with the switch pressed in for the EXP posistion, but I cannot use it in the NOR posistion. I have lost the manual for the noise bridge. What does the Noise Bridge do with the switch in the NOR posistion? What does EXP/NOR mean anyway?

Thanks

If you only need the insulators to end an antenna and not any serious strain, go to a Home Depot, Lowes, Home Base etc and go to the fence section. Find the electric fence area and you can buy hundreds of the plastic egg type strain insulators for very, very cheap. They come in bags of 50 to 100 or more and would be just fine for a simple antenna system. Such as a dipole, inverted vee, g5rv or what ever.

If you are in a city of any size, the 2" (and larger) insulators (commonly called "Johnny-Balls") can be purchased at wholesale electrical supply outfits like Graybar. I prefer the gray colored ones made by Porcelain Products. They seem to explode less often than the brown ones during a lightning strike.

Doc

I never called it anything,, I was "stating" what they are advertised as in case someone else cared to try one. Irregardless of what they are, they work quite well. They may not work as wonderful as a 250.00 ant tuner but they work almost as good as one for recieving. If you choose not to use one then dont. Ive been swling for 40 years now and in that time I have tried many different ant. systems and I am more than happy with the MLB.

Roy, W7EL wrote:
"There are several important reasons for doing receive tests instead of transmit tests. One is the unreliability of others` reports."

Sounds reasonable to be in control when measurimg for good results.

I`ve done field strength measurements in the AM broadcast band, in the shortwave broadcast bands, in the land-mobile bands, and in commercial microwave relay bands. Accurate received signal level determinations are not hard to get if one has an accurately calibrated signal source containing an accurate output attenuator (a high quality signal generator). One substitutes the signal generator to get exactly the same S-meter, limiter current, or db reading one got from the antenna. One has only to read from the signal generator the number of millivolts, microvolts, or fractional microvolts that are required to replace the antenna signal. One can make A-B tests between a reference antenna and a tested antenna.

Best regards, Richard Harrison, KB5WZI

Roy,
98% of what you say is unexceptionable but this sentence must not go
unchallenged...

A physically small antenna can radiate every bit as much power in one
direction as can another of "full" size but the capture area of the smaller
one will always give a weaker signal on receive. .Equal transmitters are not
always equal receivers.

> not.

Who said anything about "to the exclusion of useful radiation in
other directions"? "End-fire" only indicates the direction of
maximum gain. It certainly doesn't indicate radiation in only
one direction. The direction of maximum gain for this 414ft
long-wire on 75m is directly off the end opposite the feedpoint
at a TOA of 45deg.

> An unbalanced pattern does not immediately translate into an
> endfire pattern.

I modeled the 414ft end-fed on 75m. It is an end-fire antenna with
about 5.8dBi maximum gain and a beamwidth of 75 degrees that is maximum
off the end opposite the feedpoint at a TOA of 45deg. I can mail you the
radiation pattern if you like. Don't you own EZNEC?

Source record: 153673

Hi all,
This might be off topic but I feel i could get an answer from this
group!
I want to build an L-band antenna for my world space receiver. A vertical
polarized yagi would be fine. The transmission is in the range 1467-1492MHz.
The page http://www.worldspace.com/receivers/accessories.htm shows the
picture of the antenna they are offering.(I have no intention of buying it
though) How about building the 3 element yagi as shown in the page?

Any Idea or pointers?

Thanks in advance,
Bejoy.

Are you trying to use a 40m long dipole or a dipole for 40m?
The dipole formula in feet is 468 divided by the frequency
in MHz. A dipole cut for 7MHz makes a lousy 3.9MHz antenna.

Source record: 153675

Typically get a 5/8 wave. If you can handle about a 7ft long antenna, get the "collinear" 2 meter double 5/8 wave antenna from Lakeview. Inexpensive, works good.
I used a right angle mount and put it inside the truck bed right at the farthest back stake hole allowing for four machine screws in the stake hole, lock washers and nuts on the outside of the stake hole. I can email a photo if you want. I also recommend using R-8X or RG-8M minifoam rather than RG-58...about a 12 foot run ought to be right...maybe 15. Altogether, maybe $35 in the antenna and feed line apprx? Get someone with an SWR meter to verify it is set right.

I use that config for my APRS station, I have a hole in the roof nmo mount for my dualband diamond gainer for my voice rig. Sometimes I use mobile HF hamsticks mounted at the stake pocket. I use quick disconnects on the 2M collinear and the Hamsticks to change them out easily.

Good luck...

Source record: 153676

If you do some reading, you'll find that the capture area of an infinitesimally short dipole (neglecting efficiency) is very nearly the same as that of a half wavelength dipole. The ratio of "capture areas" (more often called "effective aperture" in professional publications) of two antennas is exactly equal to the ratio of their gains, again neglecting efficiency. So the receive "capture area" ratio = the receive gain ratio = the transmit gain ratio.

If you'd like to learn more about this topic, consult any good antenna text. Or do a deja search and review the postings on this newsgroup in August 1999 with the subject "Capture Area". You might also read my posting on this topic on Feb. 4, 2000, under the subject "Brand new quantum leaps in very small antenna performance".

Dang...wish I could have a 3-element 80M yagi at a 150 ft....

Guess an 80M dipole at 10 feet is fine for NVIS (near vertical incident skywave) and is similar characteristics until you get to about 60ft high anyway. Sure, you'll get some DX too.

I usually do most of the time. This was one reason why I thought it might be better to do it on 2m, rather than 80m. I think it would be quite a bit more accurate without having to deal with the constant changing of propogation. Like you say it's really hard to tell for sure on that band as it's different every night and changes from minute to minute. The only problem with doing it on 2m, is most local signals I would be able to receive would be vertically polarized. I would prefer the local stations be the same polarization as my antennas. But I guess I could get a pretty good idea which was best for the most part. I never could a/b the dipole vs turnstile on 80m as I couldn't run both at the same time with the single feedline I used. Also the dipole made half of the turnstile. Now that I think of it, I guess I could use 2m ssb. Most of those guys are horizontal. The downside is I don't hear a whole lot of them on the air these days. But then again, I haven't listened much in that part of the band. MK

3032. Re: Are their new HF bands coming???

Newsgroup: rec.radio.amateur.antenna

The proposed 60-meter band would be between 5250 and 5400 KHz, and it would be limited to domestic use only (no DX). The ARRL recently concluded successful tests, with the FCCs approval of the experiment, and is petitioning the FCC to allocate 60 meters to us. If granted, access probably won't become available for at least 3 years, more likely 5 years. Such changes are an almost glacially slow process. No other completely new *bands*, per se, are on the table at the moment. Various proposals and suggestions have been made, some very recent, to *expand* exisitng allocation on many HF bands, including 30 and 20 meters, as well as shifting the allocation for 40 meters +/-100 kHz (probably down to 6900 or so) to avoid QRM from the 1oud SWBC signals in Region 1

Source record: 153686

Doing a 2 meter comparison is fine for comparing, say a Yagi with a dipole, assuming that you can rotate both at HF and assuming the other station has a purely horizontally polarized antenna. If you're trying to compare a horizontal turnstile with a dipole off the end, though, or any antenna with a non-rotatable dipole, you can't extrapolate the results to HF. The problem is that polarization is very important when communicating by line of sight. If the other station has a vertical antenna and no stray horizontally polarized pickup (which you can't guarantee), a horizontal dipole is likely to deliver a stronger signal off the end than off the side. If the other station has a purely horizontally polarized antenna, the dipole will probably be better broadside. In an HF skip environment, the polarization rotates around in a seemingly random pattern, making polarization unimportant (except in its interaction with the ground), so in the long run only the field strength counts.

Another important consideration is that vertically polarized signals, which a dipole produces in every direction except broadside, react differently with the ground than horizontally polarized ones. At HF, you can have quite a different vertical pattern from the vertically polarized component than the horizontally polarized one. (Compare the vertical pattern broadside to a dipole with the pattern off the end with EZNEC, to see what I mean.) If you're doing a line of sight comparison where ground reflection isn't a factor, you'll again get different results than you will at HF.

Jon

I have built a number of JPole antennae for 2m. My current antenna set up is all JPoles. I have built a dual band 6/2m and a super JPole for 70cm. The Super J is a collinear of effectively three half wave sections separated by half wave stubs and J matching section. Work great!
My experience is that a JPole would have to be the easiest antenna to build a get going.

Hi Terry,

I've Use a messenger line, (Rope about 3/8 inch Poly) hang the ladder line
below that about 3 time the width of the line below the rope with wire ties.
worked great here.

I would not recomend threading the rope through the line.

Source record: 153690

What it amounts to is this. What you 'call' an
object is supposed to 'define' that object. I can
'call' my old Ford an Maseratti, but it doesn't make
it one by any stretch of the imagination. For a
manufacturor to call their product a 'balun' when it
isn't one, is false advertising, and in my opinion,
a very silly thing to do. Exactly the same thing as
a manufacturor claiming 12 db gain for their 1/4 wave
groundplane antenna...

Back when I had my novice license in 1952, raising my 40m dipole
from 10ft to 20ft dramatically improved its performance. Raising
the height from 20ft to 30ft was barely noticeable.

By the way, you can buy the hardware they use to make the Arrow, from any hunting supplier (except for the boom). The threaded ends are sold for attaching certain types of "points" to the shafts. Just knock the heads off some long 6-32 screws to tie it all together.

I plan to try this for making a 220 antenna (scaled from my Arrow dual bander). Hopefully, I can find some "reject" shafts that were not straight enough for the hunters to use, which should make this a very cheap project.

Just a word of caution -- you're using a handi-talkie, and if your antenna is too "good" it may overwhelm the front end of your ht. Some are more resistant to overload than others. The big whips are mainly designed for mobile-type rigs that come with no rubber-duckie. A whip may work fine with your rig; you'll just have to try it and see.

3045. Omnidirectional for urban use

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-30 13:38:13 UTC
From: chris-google@pobox.com
Message-ID: <ba42132e.0111300538.69bf7e97@posting.google.com>
Source record: 153693

I live in "intown" Atlanta, well inside the I-285 perimeter, and the 10 or so broadcast stations are radiating from 10 wildly different points on the compass. But, despite being intown, I still have reception problems with some stations (both VHF and UHF). I don't think it's multipath -- I far away (5+ miles) from the downtown skyscrapers and further from any mountains. My neighborhood has gentle hills (about 100 feet from peak to trough) and my house is near the bottom of one, although I wouldn't considering it steep enough or far enough down to qualify for "down in a dead spot" or anything like that, but that maybe a factor.

I currently use rabbit ears on the TV set but am planning on installing a "real" antenna in the attic. A regular directional array would do me no good due to the many tower locations, so I was considering one of those circular omnidirectional antennas just to get me a little gain. I shouldn't need much gain since I'm already well inside the covered area.

Before I go buy the thing (perhaps off eBay), should this work?

3046. Updated S Meter Software

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-30 13:48:43 UTC
From: Greg Ordy <gregordy@ameritech.net>
Message-ID: <%6MN7.5065$Rw2.3596942@newssrv26.news.prodigy.com>
Source record: 153694

I have updated my free S Meter monitoring software, located at:

http://www.seed-solutions.com/gregordy/Software/SMeterLite.htm

This program works with the radios which support remote reading
of the S Meter from the computer. That list includes the ICOM 756PRO,
706MIIG, 746, and Yaesu FT-920 and FT-1000MP (probably MKV too).

The recent update includes the ability to draw an antenna
pattern plot from accumulated S Meter data.

Greg Ordy, W8WWV

PS: nearby that web page is another that holds a set of S Meter
measurements I made about a year ago. The measurements show
that for a large set of radios, the value of an 'S Unit' is not
even close to some mythical value of 6 dB, especially at the
lower end of the S Unit range.

>meter band. I'm not real sure it's
>such a 'good' idea.

Don't worry yet - because it doesn't really work that way.

Even if one national administration went to the international Conference with that tradeoff in mind, all the national proposals are liable to be changed on the fly to get a workable deal across your whole ITU region. Region 2 includes not only the USA but also Canada and all the Central and South American countries. Each country has one vote, regardless of size.

But that regional deal is still only a proposal to the final world-wide session which resolves the interactions between the three ITU regions. Once again, it's one country one vote. Often major changes can happen at the last moment in a final flurry of horse-trading, which is probably too fast and complex for any one country or grouping to be able to control... or even fully understand what's happening. (A bit like the closing moments on Ebay, really.)

Amateur radio punches better than its weight in these conferences. Even though we don't have any votes, we do have our act together on a world-wide basis through IARU. The radio amateurs are noted experts at the "corridor diplomacy" that really gets things done.

Bottom line: whatever is currently being proposed in any one country is a very long way from a done deal.

Roy, W7EL wrote:
"What reference do you have that shows gold to be a (better) conductor
than silver?"

The CRC Handbook of Chemistry and Physics gives the following
microhm-centimeters of resistivity:

```
Aluminun.................2.824
Brass.....................7
Copper (annealed)...1.7241
Gold.....................2.44
lead.....................22
platinum.................10
silver.....................1.59
Tin.........................11.5
Tungsten.................5.6
Zinc.........................5.8
```

As conductors these metals rank: Silver, Copper, and Gold, with less
than a 2 to 1 advantage of Silver over Gold in conductivity, with copper
in the middle.

All,

I live in a townhome community (not a condo association). We own our own land, but our Covenants and By-Laws emphatically reject installation of antennas of any sort (even on our own land, not just common association property). The association is in the process of accepting written comments with regards to an updating of all our legal documents. I wish to make a case for limited, well-placed small antenna systems. Right now I'm looking for useful material to support my case. In particular, I'm looking for a general description of Amateur Radio which details the following points: 1). The difference between Amateur Radio and Citizen's Band, 2). General information on licensing requirements, 3). Emergency service and supporting documentation, etc. If useful documents do exist, I'd really rather not take the time to "re-invent the wheel" and write it all myself.

I have already scoured the ARRL Web site and found little of real usefulness, other than perhaps PRB-1. In addition, I just got of the phone with ARRL HQ, and believe it or not, they seem to have very little general information available along these lines. There is a general description on the Web site, but it has lots of graphics, is too rudimentary, and is targeted on more or less "advertising" Amateur Radio to a prospective licensee. I'm looking more for useful background information to support a possible clause to be added to the Covenants and By-Laws. Anything anyone could point me to would be greatly appreciated.

Hi Bejoy,
the "standard gain antenna" is intended mainly for usage "on a
parabolic antenna as a feed". I am afraid it has too little gain and
directivity to be pointed directly into space. Moreover, it probably
has more than 3 elements - what is inside that thick box in the center
of the boom ?
Neverteless, a bigger (say 18-element) Yagi is worth trying.

Given that silver is a better conductor, but it is subject to oxidation
and tarnish whch would (over time) decrease it's connectivity, whereas
gold doesn't oxidize or tarnish. That's why gold CONTACTS are
considered superior.

Silver wire with gold ends. Are we talkin' radio or jewelry?

Chris,
There are very few, if any, omnidirectional antennas
that have 'gain'. Most of those that do have gain are
vertical arrays that I would assume would be much too large
(tall) for an attic. You might look into an amplifier for
an antenna in your attic. They also can be problimatical,
but even so, should improve your reception.

Mark Keith NM5K wrote:
"I think it would be quite a bit more accurate without having to deal with constant changing of propagation."

It would be easy and simple if propagation variations did not have to be accounted for. Microwave measurements are like that (most of the time). Accuracy is possible over a variable path too.

Propagation variations are handled by averaging a large number of measurements taken over time.

For shortwave broadcast antennas, designs were modeled at UHF. After full-scale arrays were built, signals from them were measured at various sites around the target area.

For gain measurements, a reference dipole was erected at the same height and aimed in the same direction as the antenna to be tested. At the top of each hour, transmission was via the reference antenna. 5 minutes into the hour, transmission was switched to the test antenna. At 10 minutes after the hour, transmission was switched back to the reference antenna, and so on ad infinitum for days and weeks during hours when propagation was good. Received signal data were collected and saved along with the reception times. At the end, data for each site were separated into reception from reference and test antennas and the data for each antenna were averaged.

The average measured gain figures were the same as built and as designed.

Best regards, Richard Harrison, KB5WZI

Well what is a "balun"? It is a impedance matching device that
mates a "bal"anced device (radio) to an "un"balanced device(ant.)
So what is a MLB?? It is a impedance matching device that mates
a radio/co ax, ("bal"anced) device to a longwire ("un"balanced) device.
If it looks like a duck and walks like a duck and quacks like a duck
its probably a duck. I suspect they call it a balun because thats
exactly what it is. Its just not for xmitting. Even in your own example
both devices are autombiles and they more or less do the same thing.
Baluns dont make antennas resonate they just transfer rf. When it
comes to recieving antennas resonance isnt everything. Having an
antenna that is impedance wise matched to your reciever is. Do you
suppose the antenna on your car is resonant at typical AM freqs?
I dont think so.

I'd consider a small TV beam with an antenna rotator. You may or may not have to use the rotator much, but that should solve your problem. Any home theater type of TV dealer should be able to fix you up with something. TV antennas are coming more into vogue, what with HDTV requirements.

Do I read their page correctly? Does the "accessory pack" include 2
antennas, coax, LNA, and filter? If all that can be bought for 48
bucks, there's no way I'd even bother trying to make something.

But then again it would be easy to make a "Cheap Yagi". Do a Google
search if you are not familiar with "Cheap Yagis".

Tinned copper wire is a common commodity. It should be avoided like
the plague at RF. Unfortunately it's hardly distinguishable from
silver plated copper.

I vaguely remember coaxial cable being adevertised as "Inner
conductor :- stranded tinned copper".

Hi Scott

I live in a regular subdivision, whom long after I moved in have amended their CC&Rs to eliminate large satellite dishes as well as TV towers, Radio Towers, etc.

When I lost mine in a storm I put up a push-pole in it's stead, pending approval from the board, who hit me with a cease & desist order when I began installing a new tower.

I still do not have a tower, but a few of my antennas are up over 50 feet on poles and guyed quite securely, also pinned to prevent twist.

I had copied information from several websites and comprised a letter that I sent to them which contained excerpts from many of them. I wish I still had a copy of the letter, but since receiving it via classified mail, they havn't bothered me one bit. But I still didn't push the tower issue.

It basically said that I was a licensed emergency response radio station (which I am) and that the laws, rules and regulations concerning my operation are controlled by the federal government, which I believe has more authority than their little band of trustees.

Then I filled two pages with excerpts from like PRB-1 and other comments made in legal suits by other Amateur Radio Operators against their subdivisions and trustees.

I left the impression that I would pursue the matter legally if necessary to keep the antenna's I have had installed now for over 20 years at this location and upgrades and alterations to these antennas.

I didn't push the 'large antenna restriction clause' nor the 'tower clause' because my atty found a couple of loopholes in their nomenclature that would stop them in their tracks and we didn't want to reveal these loopholes just in case it ever came to court. And in the interim since that time, they have made modification that allow small satellite dishes and removed the words TV and Receiving Towers and replaced them with simply any Tower type structure. So my poles are still in the clear, even with a little bickering from time to time.

RG-58A cable has a tinned stranded center conductor, while RG-58 has a solid unplated copper center conductor. At 100 MHz, the (Belden) specified loss of RG-58A is 4.9 dB/100 ft, while RG-58 is 4.5 dB/100 ft. I, and I'm sure many others, find the very small difference in loss to be well worth the trade for added flexibility and corrosion resistance.

Incidentally, many silver platings have much worse conductivity than copper, although I doubt that many are as poor as tin.

I was recently discussing with someone different ideas for attic antennas as I live in a restricted area. I told him I was currently using a Cushcraft AR-2 vertical on 2m and that it works fine although I do get a little bit of TVI. He told me that that was possibly caused by the antenna I am using not decoupling the RF, cable, from the antenna or something along those lines.

So, is this decoupling or uncoupling business just a bunch of BS or is it something that's truthful? I was thinking of replacing this antenna anyways with something that performs a bit better. Any suggestions on a vertical antenna that is not more than 7-8 feet high, 2m, and not a directional type antenna (yet) or should I just stay with what I have? Thanks!!!

> suppose the antenna on your car is resonant at typical AM freqs?
> I dont think so.
>
> Jeff

The second sentence shows the 'problem'. Almost all
radios (at least those with a SO-239 connector for an
antenna) are ~NOT~ balanced devices. And by definition,
a balun is a device to convert from an unbalanced input
to a balanced output. It has nothing to do with impedance
matching.
The antenna (all of them) on my car is unbalanced, the
radio (AM/FM/Amateur) is unbalanced, and the coaxial feed
lines are unbalanced, no need for a 'balun'.
And to use your analogy, "If it walks like a duck, and
barks like a dog, I'll bet it isn't a duck."...

Roy, W7EL wrote:
"Incidentally, many silver platings have much worse conductivity than copper, although I doubt that many are as poor as tin."

If we are comparing silver plating versus copper plating of the same base metal, and if the platings are identical in depth, why would not the silver be very slightly better? Silver is slightly more conductive than copper. This reduces penetration in the silver very slightly which slightly offsets the higher conductivity of the silver, but the difference in conductivities of silver and copper is almost trivial. Roy said: "much worse conductivity than copper."

If Roy meant steel coated a molecule or so thick directly on steel (my experience with electroplaters is that they plate with copper first, then they lay on a coating of whatever else the metal is to be topped with) versus solid copper, then the thin silver might lose out in conductivity to solid copper.

If silver more than "skin deep" is layed on copper waveguide, I`d wager the clean uncorroded silver plated waveguide would have slightly lower loss than the unplated waveguide. I`ve installed both varieties. The people I installed for wouldn`t have knowingly spen`t a penny for appearance only. I recall having turned down silvered waveguide in favor of plain copper because I thought it unworth additional cost. My best recollection is that it did offer a slight improvement but commanded a fancy price which might have been used to gain more db another way.

I am puzzled.

Yes, but common mode current on the outside of the transmission line (coax) can create (RFI) problems. If you read the original post he was speak of transmission line decoupling.

Decoupling (choking) the coax at the antenna is not BS but, rather good engineering practices.

Absolutely true. The AR-2 is also an end fed half wave and is notorious for
radiating from the coax.

Sure, decoupling is critical on VHF/UHF antennas. If the coax shield radiates , then yes it can cause TVI due to antenna currents being closer to the TV's or feedlines. But the worst part is if you do have a lack of decoupling, it will ruin the pattern of the antenna as it skews the pattern up off the horizon a bit. So you could have an antenna which would normally have gain, such as a dual 5/8 collinear, actually show less gain on the horizon than a good 1/4 wave ground plane if the gain antenna had no decoupling. You still have gain, but it's not where you want it. I thought your antenna had some sort of decoupling scheme , but I'm not sure. I'm not really familiar with that model. Being the antenna is in the attic, it may not help much to improve decoupling if you have cable lines in the attic or antenna leads near by. I would probably stick with what you have, but you could test to see if a lack of decoupling is a problem with a RF probe, or try an antenna that normally has pretty good decoupling such as a 1/4 wave ground plane with about 8 radials. You could make one of those from a so-239 connector and hang if from the rafters. Never know, it might outdo the other antenna. You can also further improve with a 2nd choke or set of radials a 1/4 down from the feedpoint. But usually with a 1/4 gp, I haven't had to go that far to get decent decoupling. Even one with only 4 radials is pretty good. You might add a choke below the feed line of your present antenna and see if that would help. If the TVI is fundimental overload from the antenna itself, nothing likely will help much except moving it ouside. MK

Screaming skull wrote:
"So, is this decoupling or uncoupling business just a bunch of BS or is it something that`s truthful?"

A coax containing a potential source of interference can pass close to a susceptible receptor of interference. No ill effect is noted so long as the high-power signal remains contained within the coax, which is the normal situation. This is true so long as the antenna is far away so that the signal ariving by radiation is below the level required to produce interference. This is also the common situation because the radiated signal is attenuated 22db in its first wavelength of radiation travel and then 6db more every time the distance is doubled thereafter.

Now, the bad news. A problem may be caused by antenna imbalance which launches a transmitted signal from inside the coax back from the antenna connection via the outside surface of the coax toward the susceptible interference receptor. There is no 22db attenuation in the first wavelength of travel on the outside surface of the coax. A strong signal may be radiated from the outside surface of the coax in very close proximity to the susceptible interference receptor. You may qualify for a WATTS award (Worked all telephone+television sets).

Scott,
I've been a ham for over 25 years and I'm now the President of a Homeowners' Association where antenna's are specifically forbidden.

A few words of advice: Don't try to "educate" anyone - no one cares a twit about the difference between Ham Radio and CB or even that there is a difference. And no one cares about licensing, emergency operating, public service, etc.

You need to attack the Covenants & Design Standards from the "Federal Preemption" angle. In our neighborhood, the Covenants were worded so sloppily that they could be interpreted to forbid cell phones, cordless phones etc. Which, of course, is ridiculous. So, before I became an officer, a bunch of us threatened to go to the FCC l2#V79b o91ih1096^*&(^*&U

Hi Richard,

I can think of maybe two problem areas. The silver plate is not entirely silver and for reasons other than conductivity is a mix that is maybe conducive to keeping that shine (but being electrically inferior). The second problem area I have heard of is that the plating can suffer from a porosity in its application that drives the resistance up.

As always, in an effort to improve an already good characteristic, we may suffer from a conversion loss in excess of the boon sought.

Mercury wetting has always saved my bacon. Nobody has quoted its conductance (not that any of this matters but it is 58 times worse than copper) but few metals can equal its speed of making and breaking a circuit. Its also been a stalwart metal for both high conduction circuits and hi-V circuits (in metal vapor). My Primary Resistance Standards used mercury terminals in place of clamp/screw connection.

I guess that puts it back to using the 80m antennas with dual feed
lines. Even then I worry about the effects of the unused wires being
in the area even if they are not in use or grounded out. But I guess I
don't have to many choices. I don't think they would have a drastic
effect if I kept them all 90 degrees apart.With receiving a/b tests, I
could still tell a good bit. If I decide to try a repeat test of the
eggbeaters, I would have to do that on a higher frequency as I don't
have room for those on 80m. MK

A balun is just a special kind of transformer. It indeed,
performs an impedance transformation even if it is 1:1.
An optimum 1:1 balun for 50:50 ohms is a different design
than an optimum 1:1 balun for 600:600 ohms.

Gee, I wonder what you do for a living?

Having a strong suspicion, let me say that you could greatly improve your
station in life if you could memorize the following sentence: "Do you want
fries with that?"

Does anybody know what correction factor to use for the element length when the element is attached to the boom by screwing it to the surface of the tube at a single point. This is the attachment method used by Cushcraft UHF beams.

They haven't made that for 10 years now. I have been in the TV antenna business for over ten years, and I have never seen one. It looks like in the old catalog, that I have, that the rotor portion is the same as the current model. If its using the three wire system, you should be able to use any of the current, or even working 10 year old controllers.

Source record: 153640

I'd certainly have to agree that tinned wire wouldn't be a good idea for traps. As for tank circuits, I recall that the recommended loaded Q for an output pi network was something like 10, so it probably wouldn't make any real difference for an inductor in one of those circuits. (There might be a heat, as opposed to dB loss, consideration with high power amps, though.) I'd surely avoid using tinned wire for inductors of any sort where high Q is important, like mobile antenna loading coils, antenna tuners matching widely varying loads, and the traps you mention. Another place it should be avoided is for small loops or other electrically small antennas where current is high. But there's no problem using it for other applications like half wave and larger antennas, ground wires, or choke or broadband transformer windings.

> appearance only.
==========
I'm sure they wouldn't. They did so from ignorance. Their
"expert" engineering advisers, with shares in silver mines, had
been reading Old Wives' Tales" such as interminably plagiarised in
Practical Wireless for the last 75 years.

As you say, there are much better ways of spending money to buy
micro-bels.

Do you know there are stll many people, even in this enlightened
age, who think radiation occurs mostly from the middle third of a
1/2-wave dipole ?

Or that all one has to do to make Litz for high-Q coils is to
individually insulate the strands in common or garden stranded
copper wire, or that trees make acid rain, or . . . . . .

I've misplaced my favorite paper on the topic so can't quote numbers, but Richard's right. The metal used for plating is virtually always alloyed for platability reasons, and virtually all of the commonly used alloys have a conductivity worse than copper, some much worse. Some time if you're at the library and are bored, find a mellalurgy handbook and look up the conductivities of aluminum alloys. You'll probably be amazed, as I am, at how dramatically the conductivity (both electrical and thermal) changes as a result of adding a few parts per million of this or that metal to an alloy.

Hah,

Look at the Radio Shack Short-wave antenna kit (about $ 9 USD) egg
insulators are in the bag.

I didn't say RS hires bright people, but they do know what the cellular
phone deal and sales
of the week are.

Farm supply stores sell plastic variety, usually red in color, for electric
fence usage.

The Wireman and David RF http://www.davisrf.com/ham1/insulat.htm have them
in stock

Really depends on if a cellular company proceeded you that had a major
lawsuit or
hassle getting a tower installed.

No one wants them, but everyone wants a handheld phone.

BTW, if you do get permission for a 100 to 150 foot tower up, do not be
surprised
if you are approached for "leasing" of antenna space. Don't quote that
price, till you know the
going rate in your area

Setbacks for towers can be covered under the city electrical / safety codes,
especially if high voltage service lines are in front of property along
public street or
along alley access.

Take out the power for the neighborhood with your tower drop, and you should
plan on moving -- before your neighbors find the noose or the shotgun.

I realise I'm about to talk about the LFL1010 rather than either of your current aerials.

There's a six page comparison/review of the RF Systems LF-520 and the Wellbrook LFL10101 in the November 2001 issue of Shortwave Magazine here in the UK. It is a fairly technical review including lots of printouts of the noise floor and signal levels of each aerial across the beacon band.

After reading the review I got the very clear impression that the Wellbrook unit was a far better performer, and the reviewer says "I can see no good reason why, given the choice, a listener would not choose the Wellbrook LFL1010 every time". A similar review of the ALA1530 recently by the same author (John Wilson) gave a similar opinion of the ALA1530. The Wellbrook loops appear to have a significantly lower noise floor and better signal to noise ratio than the competition, though they do have directional properties too which may be a good thing or a bad thing depending on your intended use.

For more detail of the review you could try contacting PW Publising for a back order. Their web site is www.pwpublishing.ltd.uk/swm.

BTW, I'm probably slighly biased towards the Wellbrook kit as I've been using their ALA1530 with great success for general HF listening for a few years now.

Cheers,

Mark.

You get it from your regulating authority (depends on the country you live in) after passing an exam.Broadcasting music is not allowed,in no country.And what is 'SW' ? When you mean SWL,no.

You get a ham radio license by taking an examination. There are several classes of license, with different exams and different privileges.

No broadcasting of any kind or transmission of music is permitted. Ham radio is only for two-way communications.

By "SW" I assume you mean "SWL", or short wave listening. Anyone, licensed or not, can listen to short wave. But you have to have a license to transmit.

Maybe someone here can point you to more information about the rules for small broadcasting stations, but a ham license won't let you do that. To learn more about ham radio, what it is, what it lets you do, and how to get a license, a good place to start is http://arrl.org/hamradio.html.

By the way, "ham" isn't an acronym or abbreviation, so it's not properly capitalized. Nobody is really sure where it came from, although there are a number of theories.

Roy Lewallen, W7EL

Reg wrote:
"Do you know there are still many people, even in this enlightened age, who think radiation occurs mostly from the middle third of a 1/2-wave dipole?"

OK, I`ll bite.

The radiated field strength from a tiny segment of an antenna (so short that the current can be assumed to be uniform from end to end) in volts per meter is:
E = 60pi/d (length/lambda) amperes (cos theta) (cos omega) (t-d/c)

From the field strength (at any point) formula given above, it is seen that the elemental length of this tiny antenna segment (length/lambda) and the magnitude of the current (amperes) through it, are factors in determining the field strength. That is, the bigger they are, the more the field strength.

One might look at Fig. 23-2 in the 1955 edition of Terman`s "Electronic and Radio Engineering" on page 866 to see an incremental tiny doulet construction of an actual full-sized antenna represented. Little steps of uniform current are imagined as reasonable representations, though we know the current varies smoothly as there is nothing to make it step. If the step length goes to zero, the representation is accurate.

The current is maximum in the middle 1/3 of the full-sized antenna of Fig. 23-2. Why would this center section of the antenna of Fig. 23-2 not contribute the most to the field strength at some point (P)?

Best regards, Richard Harrison, KB5WZI

The difference between HF resistance of copper and silver is about
the same as that due to a change in temperature of 7 degees C.

But nobody loses any sleep about the reduction in Q of the tank
coil from 300 to 290 as the PA warms up from cold. Does it ever
occur to anybody ?

If anybody should iinsist on increasing coil Q, an increase in
copper wire diameter of 3% has the same effect as silver plating
and is much less expensive. But of course, this sort of news is
not suitable for filling spaces between the adverts in monthly
magazines.

Keep in mind that most of the employees at these types of jobs are not looking for a career. They are simply trying to pay their bills while they look for a career. I'm sure there has been many a student employee that became a amateur radio operator from having their interest stirred while working for companies like radio shack. Lets not be so critical of their lack of knowledge and just hope that maybe seeing some of us having fun with electronics will spark an interest in them. A big part of being a ham is educating the public.

Tom -

This question was asked last month by a high school also desiring to
"broadcast music"
I will give the short answer to these earlier discussions (which can be
found on eHam.net and qrz.com)

It is not legal to "broadcast music" on amateur radio frequencies.

Short Wave is actually short wave listening (SWL). You can find magazines
such as Monitoring at your local bookstore about this hobby.

There are two approaches for legal "broadcasting":

1.) Internet Radio (cooperative ISP)

2.) On the Air Radio station (licensed by FCC)

The first does not require a license, but does require an ISP familiar with
streaming audio origination and some equipment on your side.

The second requires an available frequency and money. There are a large
number of broadcast stations (AM. FM. TV) already on the air. In many
metropolitan areas, there are NO available frequencies. In rural areas,
there are some available frequencies for new stations.

Use this web site to find the stations in your area.

http://www.radiostation.com/kodis/

IF you want your won operation, then look at Internet Radio - very popular
in Europe, Australia, New Zealand and parts of the U.S. The only audience
restriction is the number of Internet connections. Haven't you looked at
the Media Player or Real Player "Internet radio" choices? These broadcasts
are made from a studio directly to the Internet.

My suggestion:
To learn about the "broadcast" industry look for a station that needs help.
There are hundreds of educational (college), non-profit, AM and religious
broadcast stations that restrict their broadcast hours or go off of the
air - because they have no workers or volunteers for broadcast time-slots.

Find one that meets your interest (very important) and talk to the station
manager or owner - if you are willing to learn about the industry, roll up
your sleeves for some education with little pay and have a genuine
interest - you may be surprised. Once you have a bit more knowledge and if
you desire to run your own station - look at Internet radio. [I served as

station manager for 3 such stations over the past 25 years]

You may have heard or read about "pirate radio stations". this was popular in the 1960's -- but in the Internet age -- does not make sense anymore (do you use 8-track tapes to listen to music in the CD age?).
Why would anyone want to broadcast in a 10 mile radius with a finite listener audience is beyond me, when Internet radio's only audience restriction is the number of Internet connections in the world (millions).

Right now, I am listening to a UK jazz station playing their Saturday afternoon program (6 hours ahead of my time zone) with Real Player.

Hi,

Tony G3ZRJ here,

I've got three Butternut HF6Vs fed as an end-fire array for 7 MHz, ie they are spaced 1/4 wave apart
and in one of six configurations two antennas are fed, one with 1/2 wave (x v.f.) and the other with
1/4 wave (x v.f) delay line to achieve the end fire. The system appears to work as per the smith charts in ON4UNs Low Band DXing, in that I am getting about 1 to 2 S points increase in signal in the desired direction and some nulling of the "back lobe".

a) It appears from practical results in DX working, that the system functions as a broadside array on 21 MHz., on that band the aerials are 3/4 wave spaced with a 3/2 wave delay on one element and 3/4 wave delay on the other.

Typical result was this morning when 21 MHz was open to JA (big time!) I happened to have the verticals configured as end-fire to NW to W/VE QSOs on 7 MHz the previous night, I tuned up the system on 21 MHz (on milliwatts before you ask) and called CQ (90 Watts) and proceeded to work a string of JAs, I then changed the phasing to end-fire at JA and the DX signals dropped by a couple of S Points.

I don't have ELNEC or anything like that, but I'm sure some genius out there can tell me if the configuration is just "appearing" to be broadside on "empirical" evidence or really would function that way? With the HF conditions over the last couple of days with the A and K indices right down and the flux figures high, I guess
there could be any number of paths from UK to JA for example that might mislead me into thinking I'm experiencing broadside working.

b) I have been thinking of adapting this system to provide end-fire on 20 and 15 and 10 Metres. To do this effectively I will need to use radial for each of the alternative positions of the verticals i.e 1/4 spacing on 20 and 1/4 spacing on 15. It occurs to me that if I lay an earth grid of (say) 3" mesh over the whole area occupied by the verticals and the surrounding ground I could place the verticals where I want and could thus arrange them for any band 7, 10, 18, 21, 24 or 28MHz depending on the band required. I realise that I will have to make up suitable delay lines for variousbands, although there will be some duplication on harmonically related bands.

What have I not taken into account I wonder, I expect that there is some reason why this will not be effective?

It would of course take a great deal of time and effort to lay such a ground mat soldering the cross connections
etc, but it might be worth it to be able to put out a great low angle sig on 7 bands.

Over to you Gurus

73 Tony G3ZRJ

Roy,

Conductivity testing is also done to confirm the heat treat condition
of an alloy. That is to say the conductivity of say alloy 356 is
different depending upon its heat treat condition ie T4, T6, T51
etc...

Tony:

I have had good results with my PHF-160, particularly when the sunspot cycle was low and there was minmal absorbtion on 160. Worked out 300 miles regularly in early mornings (daylight) with just 100 Watts. Bandwidth is extremely narrow - about 8 KHz at 2:1 VSWR points. On a regular 75 mile trek to my lake cottage, the PHF-160 worked as well, if not better than a Swan 50 on 80m - and the Swan is a good performer by virtue of using a large diameter loading coil and relatively heavy guage wire.

Have fun mobiling on 160 and 80m!

Most of the people at Rat Shack are not technical, and many hams
delight in going into a RS damn well knowing that the 18-yr. kid
behind the counter knows diddly about electronics, or what the
company sells in the parts isles, just to be able to put the clerk
down as being a moron.

Fifteen minutes research in a
catalog, or online, will yield the part number, which any clerk can
then look up to verify if, and where, it is in stock.

Some time ago, many schools used a 'carrier' transmitter which
used the building wiring to broadcast a low power AM signal
throughout a dorm or similar building legally.

Are these still in use or are they no longer allowed?

Everything you've said is true. The issue, however, is that RS as
a company has cultivated a market niche hungry for electronics
expertise. The slogan, "You've got questions, We've got answers,"
fairly cries out "technical knowledge." Something, at one time, RS
was well known to provide in abundance. But when Tandy, now
RadioShack Inc, moved away from hiring competent electonically
informed personell, they did not position themselves away from the
'providers of expertise' notion. Rather, they continued to cultivate
it.

For that, alone, RS deserves more than a little of the contempt
heaped on them.

And that 18 year old kid has gone out of his way to try to present
himself as a technical whiz kid, whether he knows which end of a
battery is up, or not. If you've ever heard a clerk telling a
prospective customer that a headphone is digital ready because 'it
has more megahertz' or that a NiMH battery is a new kind of Ni-Cad,
and may be used, and charged interchangeably, you'd see that many of
these kids invite the kind of abuse that old line hams have brought
to them.

RS abandoned hard electronics in the 70's. We knew it. Truth is,
THEY knew it. They've always admitted that for serious quality
components, we all go somewhere else.

Even so, they've continued to present themselves as the 'experts'
in electronics.

It's an open invitation to the kind of childish abuse you
describe.

And as we all know, here, there are plenty out there who live to
provide it.

Peter:

> The slogan, "You've got questions, We've got answers,"
> fairly cries out "technical knowledge."

i agree... in the past many of the guys behind the counter were hams or 'into' electronics and knew a great deal. maybe their new slogan should be "You've got questions... We've got cellular phones with 50% more gighertz.".

i know that inside we're not bashing Rat Shack... we are instead mourning the loss of competence behind the counter... some still exists but its like the taliban... in small pockets. sadly if the trend continues your trip to radio shack might look like this someday: in the store window you notice a sign that says 'no germanium diodes, go check the bakery next door'. then you open the door to the 'the shack' and carnival music starts. upon entering a clown with a big nose that looks like a cross between big bird and ronald mcdonald's evil twin will greet you and say 'how about a cellular phone? little partner.'... then he'll squeeze his red nose... *beep beep*... to this you'll say 'get lost bozo' and then whisper to your kids 'avoid eye contact with the lunatic while i get some of them fine 1 mAH green batteries'. 'Bozo Shack, We've got cell phones!'

reminds me of a benny hill skit:

benny: 'what's he got that i haven't got?'
girl: 'well, he's got wavy blond hair'
benny: 'well, I'VE got wavy blond hair!!!'
girl: 'well, he's got strong white teeth'
benny: 'well, I'VE got strong white teeth!!!'
girl: 'well, he's got brains and intelligence'
benny: 'well, i've got strong white teeth'

phil :)

'You've got questions? We've got strong white teeth!!!'

Anyone that has such a low opinion of himself that he has to put down an "18 year old kid behind a parts counter" in order to feel "smart" is in such sad shape as to deserve our pity and "many" hams do not have time for such child like behavior they are too busy helping on the community with Sky-Warn, and other activities.

And since they pretend to provide it, our chances of buying good electronics parts elsewhere gets smaller and smaller. It's bad enough there are only a handful of places we can buy ham radio gear now, and that the CCR's and other things are making it impossible to work HF in many urban areas. When I was a kid, listening to Dad's old S-38 was something close to magic. Now kids have cellphones, the internet and satellite TV. SWL'ing and DX'ing hold no excitement or magic for them. Tbey think cellphones and satellite TV ARE electronics, and all that is really important. They don't know any better. I'm not sure we can teach them any differently. There will always be a few that will reach out of the mainstream, but those will always be few.

Hi Tom,

I'd suggest you try some amateur radio sites such as ARRL.com or ARRL.org. You might also try a web serch using the peramaters amateur radio testing or ham radio testing. As far as a ham station, you can set one up for less than $200 for 2 meters (that's how I started) It takes a bit of work to upgrade to a higher class license but you'll f ind that it's a GREAT hobby. If I can be of any service let me know. One of the coolest things is that you get your own personal call letters. Unfoprtunately you're not allowed to broadcast music over the air, but you can have some very interesting conversations (commenly called a "ragchew")

another great site is qrz.com tons of info and practice tests you can take

73's (that's ham-speak for "warmest regards")

I think they are still allowable but FM certainly took a toll on that scheme. Every one I ever heard was severly afflicted with 60 cycle hum. I recall an instance, I think it was in Ocean City MD, where somebody installed these things at various locations along the 'strip' to provide coverage to the vacationing market. I forget how it was dealt with by the FCC.

I had a GEM many years ago. 50 feet up and I could run even or better
with a fellow ham's TH6DXX at the same height. I always had less QSB.
It wasn't a heavy-duty engineering marvel and I wouldn't want one 100
feet in the air in an icy location, but it was far better than I could
do trying to homebrew one.

I'd like to install a trunk mount V/UHF dual band on a 2001 Honda Accord (sedan). I've decided to go with Larsen since I've had good experiences with their products in the past. Being new to trunk mounting (I have only a vague notion of how these things arre supposed to look like mounted), I was wondering if I could get some suggestions from those who have used trunk mounts on similar-type cars about which model mount to purchase, i.e., NMOTLP, NMOTLB, or NMOTLB, and what model whip to use with these.

Thanks in advance,
-Robert

Our community finds the Slywarn program to be rather valuable, judging by the support that the county council has shown. But, I still find time to teach licence classes, and I'm waiting for my VE to come back from ARRL.

Of course my RS guys are all quite nice and relatively intelligent.
It must suck to live in your part of the universe.

Hey Reg, is that average the mean, median, or mode? :-) Seems
to me a step down transformer doesn't transform the *average*
impedance Vs frequency. :-)

Doc, W5LZ wrote:
"Do ~ you ~ see the phrase "possibly caused by the antenna."?"

Yes, and it is a real possibility.

Suppose you have a simple dipole which is unbalanced. Off-center feedpoint may cause the imbalance. The antenna then supplies signals of unequal magnitude to the outside of a coax feedline or a common mode current to a parallel-wire feedline. This net current radiates as it flows in the feedline, on the outside surface of coax, or as an unbalanced current in a parallel-wire feedline.

The unbalanced current on a feedline passing in close proximity to sensitive electronic equipment can play havoc with operation of the sensitive equipment.

The culprit was the antenna in the example cited. Balance the antenna and eliminate radiation from the transmission line.

Best regards, Richard Harrison, KB5WZI

May I suggest that you consult with the manufactuer befor you do any altering on that antenna. It's possible that the manufacturer has already carculated a windload in excess of what you will meet.

If you make the verticle too stiff, it may snap. Something to consider.

Peter:

The latest implementation of that scheme is: "Talking houses", where a low power transmitter is set up by the Realtor which runs a tape loop describing the features of the house for sale. I think I picked up one of those boxes at a garage sale a while back for a buck or two to see what was in it. It was complete with a loaded whip antenna (~1% efficient, probably) and the cassette machine. I haven't seen it lately, so it may have wandered off with a visitor to the shack (I hope). This thing had an AC power cord, and operating instructions printed on the front. VFO covered the top half of the AM band, maybe to 1700, with instructions to set it on an "unused channel in your area". Seemed to not have hum like the carrier current devices, one of which I built and operated for the campus radio station in the 50s. Cassette audio was lousy, though.

3146. FS: SMA-to-BNC custom fit antenna adapters

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-02 03:14:45 UTC
From: gulyas@earthlink.net
Message-ID: <12235960.0112011914.5792baa2@posting.google.com>
Source record: 153596
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.swap,rec.radio.scanner

Do you have a need for a high-quality SMA-to-BNC antenna adapter that
is custom made to fit and protect your H.T. or scanner radio?

Adapter allows you to:
Quickly change antennas to base,mobile or different style use.
Use the more popular and wider selection available of BNC antennas.
Prevent chassis connector wear or from coming loose due to antenna
changes.

Adapter features:
Gold plated contacts with a teflon insulator.
A low profile design with a rubber covering for a factory antenna look.
The rubber base seals to the top of the radio with no spacers needed
for moisture and dirt protection.
The base also provides an excellent support for any length of antenna
or application.
No need to remove adapter once installed to make a quick and safe
antenna change.

Sizes to fit radio models:
Yaesu: VX-5, VX-1, FT-50-R, VX-10, VX-150, VX-110, VXA-100, VXA-120
Icom: IC-T8A, IC-T81A, IC-Q7A, IC-R2
Kenwood: TH-D7, TH-G71, TH-F6A
Alinco: DJ-V5
Standard: C508A, C510A
Radio Shack: HTX-200, HTX-400, HTX-245
Aor: AR-16

Previewed in the May 2000 Issue of CQ Magazine, and the Nov. 2000
Issue of QST Magazine.

$11.95 + $1.50 S+H(One to unlimited)
(Check or money order only in U.S.Funds)
(Specify-radio-model)

Depends on the noise level more than anything I bet. I haven't seen
that antenna , so don't know how well it would do. The fatter the coil
it uses the better. You could make your own. Just take a higher band
hamstick and add your own fat loading coil. I use various versions of
these here. One is an all band version built from a scrap 11m
firestick CB antenna. It uses a fat 80m coil which is tappable for
40m, and I bypass the coil and vary the stinger for 30-10m. I might
make a 160m version . I would look for the tallest stick I could find,
such as 6-7 ft, and than add a homebrew loading coil about 1/2 the way
up. The coil will be quite long. For 160m, I would use at least a 4
inch form, or even bigger. The problem is weight and windload. You
would want to use the tallest flexible stinger whip you could manage
attached to the top. You could also clamp on little "hat stingers". I
use a 4 ft stinger on my 80/40 setup. The stick is 5 ft, so 9 ft
total. With junk parts laying around, you could build one for next to
nothing. I've been using grey PVC to use as coil forms and haven't had
any trouble. I've test cooked the stuff in the microwave and had no
heating whatsoever. The grey type is supposed to have no metal
content. I've also used thin plastic tubes. Normally, I use pretty
thick wire like #12, but for 160m, you will need to keep the weight
down or it will flop around like crazy. So I'd use a bit thinner wire.
You will have a lot of turns. You could probably make one for 25-30
bucks even if you had to buy a new high band stick to butcher up. And
should work as well or better than the 100$ version. It's up to you
and how well you want to make it. Also you will need impedance
matching of some type. Most all the people I've worked on 160m used
bugcatchers with large coils. I used to work one on the other side of
town that ran one with a 9"x9" coil. Also ran a metron amp. He had to
use a large corona ball to keep the lightshow down. At about 25 miles
away across town, he would average 30-40 over 9 every morning. As loud

as many house stations. Louder than some. I've worked quite a few
others. Most all run a bit of power if they want a reliable signal.
But it doesn't take a whole lot. Just getting up in the 500 w range
will help a lot. You can't use a bic lighter to broil a steak on 160m.
:/ MK

Don suggested that Irv consult his antenna manufacturer before beefing up his antenna. Maybe that`s a good idea. I don`t see how it could hurt, but wouldn`t expect the manufacturer to endorse strengthening the antenna. It would be an admission that the manufacturer could have done better. A bigger problem for the manufacturer is concern for the competence of the modification plan and its execution.

A good manufacturer issues field modification bulletins for improvements that are fully worthwhile. The manufacturer may not have your address, so contacting him would enable him to inform you if your antenna needs field modification or recall for improvements or replacement.

Materials that are formulated or treated for stiffness may become brittle and take fewer flexures before failure. Structural members augmented excessively can become overloaded due to the accumulated dead-load this causes.

But, adding strength with light-weight stiffners tends to limit flexure, reducing fatigue and failure probabllity in most cases.

I am not a structural engineer and am only offering an unqualified opinion. Don`t sue me.

Best regards, Richard Harrison, KB5WZI

I'd really like to know the source of the info about the supposed loss of part of 75/80 meters. I haven't heard anything even suggestive of that, and while I don't read everything on the FCC's website about allocation changes, I do keep fairly close track there and via the ARRL. Keep in mind that part of 75/80 meters is a SWBC band in Europe and the Middle East. Perhaps that is what is being referred to. There was a ruckus about 2 years ago over a certain religious broadcaster in Germany QRMing 75 meters. A lot of American hams, perhaps new hams and not aware of worldwide allocations, complained to the FCC about this signal. As it turned out, it was winter and propagation just was favoring the little (by SWBC standards) 5KW AM signal. Just as the US 60 meter band will be (we hope) for amateurs, 75 in Europe is for broadcasters. That is, it is for domestic use only. The FCC actually is in the mood of giving hams for HF space, even suggesting it first in some cases. Perhaps this is a savvy way of avoiding criticism when they try to sell off VHF, UHS, and SHF spectrum to commercial interests. They can claim that they are generous, and that we are greedy.

Some baluns do function as impedance transformers, but that is not what they originally, or essentially are. They are devices to connected an unbalanced source (usually) to a load which functions with currents balanced in each pole with respect to ground. The MLB device perhaps is useful, but it is probably not very good as an impedence transformer, give the greater than 10:1 range that most SWLs tune, and given a single antenna. The line to antenna mismatch *ratio* at 49 meters is going to be veryt differenet from that ratio at 25 meters, and so on

Hi,
Tony G3ZRJ here again,

1st December 2001.

I've had a couple of requests for details of the phased vertical system,
I've replied direct to the enquirers
but thought others might be interested and hopefully can contribute.

The design is adapted from "Steerable HF Antenna" F.E. WYER G8RY Practical
Wireless January 1984
reprinted in Wires and Waves, A Practical Wireless publication 1984.

In F E Wyer's article he uses three verticals with Gamma matching for 21
MHz.
I wished to adapt the design for 7 MHz and having got 3 Butternut HF6Vs
which present a good 50ohm
load, I decided that the Gamma match would not be necessary and proceeded to
follow G8RYs design in
all other respects.

I intend sending the design to our RSGB magazine as it may be of interest to
others.

The essential points of this three vertical system are:

The system works as an end-fire array in six directions, each employing two
of the verticals, the two verticals concerned "fire" in the direction of the
antennas which "lags" in phase with respect to the other.

Assuming your verticals are located at West North and East compass
directions from a baseline between the
East and West antennas N

W E

my system works as follows:

Beam1 NW
Beam2 NE
Beam3 SE
Beam4 SW
Beam5 W
Beam6 E

1) Three identical verticals with as near identical radial patterns as you
can manage
a) If using buried or on-ground radials the lengths don't need to be

precise since the ground will detune them
however, make then 1/4 wave or more if you can.

2) Feed each vertical with an identical length of coax (I use milspec RG-213), according to the article an odd number of 1/4 waves of feeder is desirable,but this is not essential.

3) Make up one delay line of coiled up coax which is 1/2 wave x velocity factor eg for most coax like RG-213 or RG8U the velocity factor is 0.66, thus for 7 MHz, 1/2 wave = 66 feet x 0.66 = 44 feet.
Make another delay line of coiled up coax which is 1/4 wave x velocity factor eg 7 MHz = 22 feet (see above).

4) using a T adapter with one PL259 plug and two sockets, or vice-versa, take the TX to the common connection on the T adapter, to one of the other connections attach the 1/2 wave delay line and label this "Lagging", to the other connect attach the 1/4 wave delay line and label that "Leading".

This is the table I've made to remind me which antennas to connect to which of the Lagging and Leading phasing lines remembering that "array" fires in the direction of the "lagging" antenna

BEAM 1/2 Wave (LAGGING) ANTENNA 1/4 Wave (LEADING) ANTENNA

NW NORTH
EAST

NE NORTH
WEST

SE EAST
NORTH

SW WEST
NORTH

W WEST
EAST

E EAST
WEST

It is easiest to construct a switch box to enable rapid switching of the beams however, at present I'm still manually changing the feedlines.

In theory, this system should provide approx 3 dB gain over a single vertical in the "beam" direction and a decent null in the opposite direction. Practical results to date (I've
only been using the array for a week) suggest that there is a 1 to 2 'S'point advantage in the "target" direction. I'm not convinced that there is quite the back to front advantage that I expected.

At present I have not matched the radial patterns of the three antennas, my "original" HF6V has in excess of 150 radials of between 20 and 30 feet. The "new" HF6Vs have 32 radials of approx 30 feet. I suspect that the

system will function better when all three antennas have "lots" of radials.

Here my practical experience with HF6V vertical operation (applies to other types) is that several thousand feet of radial wire makes a real difference, I agree with those who tell me that in theory I'm just wasting my time with more than a few tens of radials. All I know is that when bands have "closed" for DX, I have still made contacts with comments like "your the only station out of Europe". My attitude is now "if it works, it works".

I hope that this helps

You'll find an explanation of the poor front to back ratio in Chapter 8 of the ARRL Antenna Book. Anyone interested in phased antennas might also take a look at "The Simplest Phased Array Feed System -- That Works", in the ARRL Antenna Compendium, vol. 2. The programs shown in the article (both source and compiled executable code) can be downloaded as SIMPFEED.ZIP from ftp://eznec.com/pub/.

If RS is going to push their advertising slogan "You've got
> questions, we've got answers," they damn well should hire personnel who
can
> provide those answers.

Picky, picky, picky. Their slogan is just advertisement and for a large percentage of the dumb clueless people that walk through their doors with a question, they have the answer and do remarkably well. Just stand there and listen to the majority of the customers ask a question. Example: " I need this thing-um-a-bob that hooks onto this other widget that makes this other thingy go around, and non of it came from Radio Shack. Oh, BTW, my seven year old hit it with a hammer and decided to take it apart and lost half the parts, especially all those springs. Can you help?"

You must really go into orbit when you hear other advertisements, such as " Built Ford tough....." or "Built like a Rock...." or " Just like Grandma used to make..." or "Farm Fresh...." or " this food is good for you..."

I bet ya a Radio Shack floor person knows more about what is in their store and how it works than a car salesman/real-estate salesman. The intelligence of a car salesmen and real-estate personnel, now there is a whole newthread.

>
> I don't blame the employees; it's RS corporate management's fault.

Like I mention above. You better be bitching about all the rest of society/corporations/advertisement firms/slogans

Skyscrapers, towers and all vertical structures are actually expected to
sway in the wind abit. As Don mentioned below, stiffen it too much and
you change its design characteristics.

If the wind sway is of concern ... consider fishing line for guy lines to
limit
it a bit.

You still see a few of these, but most have been removed from colleges and
schools
in favor of low power FM or Internet approaches.

When you go to the arrl.org web site -- look for a club or the licensing
organization in your area.

Go to one of the meetings. Many areas have regular classes for people
desiring to become
amateur radio operators.

Point well taken! And of course we have all had fun with our own
interpretation of those slogans.

Burger King - Have it THEIR way!
Ford - Found On the Road Dead!
Or my favorite when I owned my Fiat.... Fix It Again Tony !

I think we have all seen the expertise level dropping in all consumer sales
fields. Lets face it, if a kid knows his stuff about electronics, he can
make twice the wages offered in the sales field by putting his knowledge to
work in the field.

Ok on the GEM QUAD. Mine is not up yet. I bought it second hand.
The Gem quad however is a good quad (this from verbal feedback over
many years from many owners.) The Gem quad has unique spreaders..that
are really three separate fiberglass sticks that are reinforced by a
fiberglass twine..thus both strong..lightweight and offer a low wind
resistance.
On the down side of the Gem Quad..I heard one report that the aluminum
spreader center piece cracked on one chap during an ice storm..and he
built his own much stronger center piece..but this is only one report
and i llive in Canada where we get freezing rain ect.
One other down side..I have seen a nice gem quad where all the wires
were broken but the spreaders were still intact.
The fellow was getting up in years and found it hard to climb his
tower. This was after our "BIG ICE STORM in 1998".
I think ..generally..quads..are higher maintance antennas.
Im going to put my GEM QUAD up this spring..and Im only putting
it up on a 32 ft tower and I plan to put some sort of catwalk or
something ..so that i can work on the antenna in comfort and try some
tinkering.
The good part about the GEM QUAD too..is you have optimum spacing
or the elements and I will add a 6 meter quad to mine..so you can
cover all the upper bands with one antenna. 73 Earl VE3AB

Start with one of those '100-in-1' Electronic Project Kits from Radio Shack (the ones with the springs). They inevitably have an 'AM Broadcast Band Transmitter' as one of the projects. They also have strict instructions to not use more than ten feet of wire as the antenna (hee hee hee). I'm still awaiting (since 1975) my first reception report - mail must be slow. I was so sure that someone would have picked up the signal. :-)

Though I'd like to talk with someone who is not "electronic challenged" at Radio Shack I suspect we shouldn't really expect that. At today's rates I don't think it feasible nor necessary to hire techs for the sales positions. I'll conceed that if they imply expertise they should rethink their advertising campaigns.

Radio Shack stores contain two basic types of material. Components such as caps, solid state devices, connectors, cables take up much of the inventory while the balance are consumer electronic devices. I think it fair to assume that a customer seeking a component has the necessary degree of competence to know what he wants and why. Just as we don't expect McDonalds order-takers to be chefs when we select from a menu why expect a sales clerk to be a tekkie when we plop 2N2222 onto the counter? We don't expect the TV salesman at Sears to be a qualified repairman or the Chevy salesman to be a mechanic in the case of consumer products.

The Radio Shak kid (or other) is simply making a buck, often has no expectation of staying long enough to call it a career. Maybe we, as hams, should take the opportunity to offer some of our knowledge rather than place our noses in the air when we go to Radio Shack.

Excuse me for butting in again...when I got mine, admittedly back in the late 70s, it was after a homebrew design. A local fella had split and bent some heavy pipe to make 'hubs' for quads. I initially bought the GEM spreaders alone as opposed to going with bamboo or whatever. In spite of how heavy his 'split-pipe' was, it turned to butter once a long spreader was clamped onto it. I eventually decided to do it right and went back to GEM to get their actual hub. It was adequately stout, but its not hard to imagine any aluminum or aluminum weld fracturing. There's a lot of stress on the hub.
The spreaders themselves are great and lightweight. I only used it for about 5 years and deterioration of the fiberglass/epoxy was a non-issue for me.
The kit back then supplied little weenie ty-wraps for attaching the wire...thats a no-brainer to re-engineer...I used scrap wire to tie the loop to the spreaders and passed the loop-wire THRU the openings in the spreaders...no way it can fall off unless it breaks.
I don't know what wire they supply, but I used 12 or 14? normal solid wire and didn't suffer any breakage over the years but I suspect that stranded wire would be preferable.

I imagine that wire and its attachment method is a concern with any
quad. Ideally one might consider 4 pieces of wire tied off individually
with little connecting jumpers at the corners.

I think alot of us did the same thing in our early days. I remember in
junior high school daze, hearing a signal up around 3 Mcs that appeared
to be local. It turns out that it was another fella, from the same
school who I didn't know, running his little station. He transmitted on
670 which I couldn't hear at my distance (about a mile) ut he got
reports on his harmonic freq from clear across town (Charlotte).
His xmtr was some rig from an old drive-in movie setup and must have put
out a few watts...antenna was a neck-high 20' piece of wire between two
dogwood trees in the front yard.
I got me one of the Knight xmtrs and went on the air after school but
never had coverage like he did. :-)

There are few commercial short-wave broadcasters in the United States.

Short-wave broadcasting is VERY common in Europe and Asia.
Think of the old USSR broadcast challenge (12 time zones !!) to get news
and government
information to such a large land mass.

Pickup a copy of the magazine Monitoring and turn to their commercial
broadcast directory - filled with stations
from around the world.

If you have a 40 meter receiver, switch on AM and listen some evening
between 7.2 and 7.3 MHz
you will hear the European broadcasters. Radio Moscow is usually the
loudest (> S9).

IMHO there are way too many. Unfortunately the majority of them fall into the right-wing or religious fanatic category. A common complaint from new SWLs is that all they can hear are Bible-thumpers interspersed with ads for "survival kits", $100 LED flashlights for the End-time, and of course HGH, the Human Growth Hormone. By law, shortwave broadcasting to the domestic audience is not permitted in the US...all applicants must specify international target zones.
In the worldwide scheme of projecting an appearence to the rest of the world, these private SW stations are nothing but a major embarrassment.

Hi Chip,
MFJ makes the "Tri-Band FlexiDuck". The part number's MFJ-1720S and costs
$29.95. It's a 19in. tri-band with an SMA connector for HT's like the
VX-5R. As advertised, gain is as follows:
5/8 wave on 440MHz w/ 3.2 dB gain
1/4 wave on 144MHz w/ 2.15 dB gain
1/4 wave on 6 meters
I'm not sure why I've never heard anybody else discuss this antenna.
Usually, they cite the Premier (Pryme) RD-78 or RD-98SMA as excellent dual
band antennas.
The RD-78 advertises 3.2dB & 2.15dB gain on 440 & 144 respectively while
only 15 inches. I believe the RD-98SMA boasts the same gain figures and
measures 17 inches (yet, it's the super-flexible, "tie it in a knot" type.)
What I want to know is: if gain figures are the same, do the Pryme
antennas (especially the RD-98SMA) work on 6 meters?

Why don't some of you guys who have trouble with the level of expertise that you find at Radio Shack go to work there and see what you can do about improving the situation?

LOL! I was waiting for this. I did. I tried working there when I was in high school. I was not hired specifically because I was overqualified. These were the manager's words. This was in the late 60's.

I tried again part time some years again, and during my 'orientation,' was told by the manager, "You don't always have to be right. It's not rocket science, and these people don't know what you're talking about anyway. Throw around a couple of buzz words, tell them it's Digital, and ask for the sale."

This was the same manager I watched take a return of a receiver that had failed, put the new receiver in the customer's old box, the old receiver in the new box, and returned the new box to the shelves at full price. "Someone will buy it. Otherwise we have to eat it, " was his explanation.

I've seen this done in dozens of Radio Shacks throughout the Midwest, and have had manager's admit to it in several more.

I did write a letter to Fort Worth about this practice on a number of occasions. They sent me a free battery card.

What's interesting here, and the source of the conflict, is that RS has continually positioned themselves as a place where one can go to get answers in matters of technology. And yet, as a culture, they avoid anyone who actually has answers. This is certainly not the 18 year old's fault. It comes from, either by design or default, the corner offices in Fort Worth. What IS the 18 year old's fault, is that he/she doesn't take it upon his/herself to get smart quick. When I tried pointing out to one clerk that transistors and IC's do not need to be periodically replaced like vacuum tubes, I was asked, "what the hell do YOU know about it?" Not the sign of a hungry mind.

One other point that was brought up during this thread was that RS clerks know more about what's for sale in their stores than car salesmen know about their products...

This, too, is false. Time and again, I've watched a customer walk into a RS ask for a product and the clerk has to ask the manager if it's available. Usually while standing in front of the product on the shelves. In one more or less hilarious incident, a customer came in looking for a cell phone accessory, I believe it was an earpiece/boom for a Nokia. (They sell them there, btw. Jabra is the brand.) Anyway, the customer was asked "what kind of phone?"
The customer replied, "Nokia."

The clerk said, "Oh, I'm sorry, we only handle Verizon."

He said this standing in front of the Sprint display.

So to repeat: Yes, there are those of us who have tried to bring technical know how to RS.

The truth is, they didn't want it.

This problem is unfortunately in every audio/visual store in the land. Go to Best Buy and try to get some answers. . .Hell go and try to get any of the sales people to even talk to you! Before I buy anything now, I go to the Internet and newsgroups and do copious research. The problem is, even if you know what you want, the salespeople do not even know where to find it in the store. I think they should at least know where to look. If I am doing a mod, I get so excited that I want to be in and out of RS with product in hand ready to solder. . .Not standing around watching the salesperson look at the catalog.

Thanks
Greg

My personal preference would be a NEMA L6-20R receptical. The L prefix specifies a "locking" type commonly referred to as "twist-lock". This type prevents the plug from accidentally being pulled, The other upside is the L6-20R has more contact serface than the 6-20R so there is less heating at the plug. But then my background is also high availablity computer installations.

The standards dictate that you shouldn't have a preference. For "x"
amps use "x" receptacle. A savvy insurance company can nail you on that
when your Xmas tree catches fire. "House suffered improper electrical
installation".

To answer your question about floureecent light - they are are more
voltage sensitive and tend to flash more than flicker.

As the previous reply indicated. Most likely, unless half your house is
on the same circuit (often happens in older homes with remodels), you
have a loose connection.

Likely canidates are wire nuts that have popped and are not forcing
wires to bond. Usually, as the result of trying to splice too many
wires in one joint. Sometimes a couple of nutted joints pigtailed
together give better results. A common poor wiring practice is to use
the "quick push" connections on receptacles. Outlets are chained
together by pushing wires into the backs of receptacles. The contact
area for the wire is pretty minimal.Better to wirenut in a pigatil wire
that connects to the receptacle's screws. Another problem I have seen
is a breaker that is arcing at the bus bar in the panel.

As to finding the problem. A quick method I have found is to plug in
a 1500W heater in place of your transmitter. This places a heavy draw
on the circuit. Usually you can find the bad connection either by
hearing the buzz of it arcing or heat from a high resistance joint.

By the way while your checking things out, verify your ground joints
too. These are often dangerously improperly done and can bite you.

I have seen some pretty rotten wiring in my day and unfortunately
half of the time it was don't by a homeowner that didn't know better
and the other half by an electrician that is suposed to be licensed to
know better.

No, but I *do* expect them to know which items have onions in the
sauce, etc. They usually do, too, since management doesn't want to be
sued by a customer who found out the hard way that they were allergic
to a product the counter guy told them would be ok.

How many car salesmen are going to keep their jobs very long if they
don't make at least a basic attempt to learn the features and specs of
the models they're selling? Most of the new car salesmen I've dealt
with could at least quote the specs and identify all the major
components under the hood.

I won't argue the point that RS should encourage employment of, and
offer some degree of training to capable people but the new car business
is quite different and attracts a 'career' mentality :-)
Such is life when the commission on a sale may be worth a couple grand
versus a part-time minimum wage job. Apples and oranges.
The only moral here is don't buy a new car from a RS employee....and
don't buy a cellphone at the car-lot.

> covers 6m?

You're right, the SMA-503 is 2M/440 only. I never used the 6M
feature on the HT, figured I'd carry the factory antenna around in glovebox
or whatever in case I wanted 6M Tx capabilites. I like the 503 because of
its superior performance on 2M and 440 compared to the Yaesu antenn, plus
its low profile (thin) is better. Works great on my TH-6A now, too.

At a Ham Flea Market yesterday I picked up an MFJ-259B with case for $175 (Canadian -- about $125 US)!!! It is in perfect working order -- but I did have to clean up corrosion from a leaky battery -- but it was just in the battery holder, and did not spread to the circuit boards or anywhere where it could do any damage! Now I can have some real fun.

One of the things I have been playing around with is trap antennas. I was going to buy the dip meter coils, then thought that it might not be difficult to roll my own. Does anyone have the recipe?

We have about 10 inches of snow on the ground now, so the weather is ideal for antenna work <grin>.

Thanks in advance for any assistance!

3195. transmitting without antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-02 23:10:18 UTC
From: Lou <lo-6@nospam.com>
Message-ID: <uxyO7.73628$Ze5.41896544@news1.rdc1.md.home.com>
Source record: 153547

I recall on many occassions reading/being told not to operate any sort of transmitter without the antenna connected. I thought about a few basic amplifier designs to see what this would do to the transistors, but I couldn't see any harm it could do. I'm no expert on this but my thoughts seem to boil down to if there is no antenna, there is no drain, so the transistor can set up the desired voltage with less current, and everyone is happy.

Am I looking at this wrong? Can someone explain an example where this isn't the case?

Thanks,
Lou

I was always confused by the shorter antennas having a lower input Z. If the trend continues all the way down to an infinitely small antenna, then an empty connector (open circuit) is a dead short...

:-)

What if the transistor was trying to feed a current into an open circuit ? Then the voltage would reach infinity and damage the transistor.

Hi Bill,

Not a fair response because we've all done it without the benefit of
curiosity (and for no good reason why to boot).

Hi Lou,
If I'm not missing your point, your question is basically, "How does transmitting without an antenna harm your transmitter?" I'll give you a simplified version.
The antenna or load is what resonates to allow the transmitted energy escape your radio out to the spacemen monitoring us since the forties:)
And, a good antenna should give you a low SWR (Standing Wave Ratio: the ratio between what goes Forward to the world and what's Reflected back to your radio). Basically, the further from the antenna's resonant frequency you get more reflected back into your radio than emitted to the spaceship.
If you don't have any antenna, your SWR is infinity and everything's reflected back into the radio's circuitry. If you're running 100 watts, it's like plugging the antenna into a light socket. "No drain" but no escape either:)
I might've missed your point here (hope not) since you mention amplifier design, which I understood in principle while studying but never learned well enough to explain in detail. Anyways, I hope this helps.

I guess that I wouldn't per se want to. But if someone tells you not to do
something it certainly makes you wonder. I guess you could say, it makes me
question how well I understand amplifier design.

I've heard from some local hams that the 503 works well on 220 MHz,
even better than the factory TH-F6A antenna ...

Food for thought,

Shorter antennas have a lower input R but a higher input X which
equates out to a *higher* input Z. Z^2 = R^2 + X^2 where X^2
goes up faster than R^2 goes down.

First off, thanks to all who replied.

Now that I've got a general idea of what I want to do, I need some more info...

Where can I get suitable variable caps for this project? Would it be a bad thing to use a variable resistor across a fixed cap for the variable capacitance, or should I hold out until I can find some air core varicaps?

I already have an idea of how I want to do the inductor, so that's not really a problem (if it works, and if I can make it mechanically strong enough).

Thanks again...

You are looking at it wrong. Go back to square one and think again.

Example 1, if there's a Pi output network and the external load is disconnected then the output transistor sees a zero-resistance load at full current and blows up.

Example 2, if the external load is short-circuited, in order to keep full current flowing into the very high inductive network reactance an excessive voltage is developed across the output collector which then breaks down.

Depends on the class of operation, the amplifier design, matching
network--if used, etc.; lots of variables, lots of possibilities. I
supose
one could use the output from a LM380 audio IC directly on LF QRP,
and see no difference if a load were connected or not.

Doc, W5LZ wrote:
"I think it would make very good stuff to spread on a garden. Antennas do not cause TVI."

TVI possibilities are increased by poor shielding, poor line filtering, improper operation, and antenna system problems.

TVI can be radiated from a faultless antenna. The TV set itself can be the culprit and the interfering station can be faultless.

Antennas can be the source of radiation which results in TVI. Oh yes, the transmitter generated the r-f, but the interfering r-f may be sensed as coming from the antenna.

A faulty antenna, perhaps unbalanced, can cause transmission line radiation. TVI to sensitive devices near the transmission line may result.

Agreed the primary source was the transmitter. Kill the transmitter and the TVI is gone. The radiation causing TVI can come directly from the transmitter, its wiring, or the antenna.

The original question was:
So, is this decoupling or uncoupling business just a bunch of BS or is it something truthful?"

Nobody contradicted the unbalanced antenna idea implicating the antenna as a possible producer of feedline radiation.

Without correcting the antenna imbalance, radiation from the antenna feedline may be stopped. A balun between the feedline and the antenna may do the trick.

So, my opinion is the opposite from Doc`s. Decoupling the common-mode signal from the feedline is not BS in some TVI cases. In cases of TVI caused in part by proximity of the feedline to sensitive TVI receptors, decoupling the coax exterior by a balun is not BS.

Best regards, Richard Harrison, KB5WZI

Interesting, I've heard there is something like a 300% employee turnover at
fastfood establishments. Just how much do you think they care what has
onion. Management is more concerned about how will they staff the next
shift because of this turnover and nomadic workforce.

Before I buy anything now, I go to
> the Internet and newsgroups and do copious research.

Good advise. I've been doing that most of my life.

The problem is, even
> if you know what you want, the salespeople do not even know where to find
it
> in the store. I think they should at least know where to look.

Hmmm, most of the time, I tour the store and pretty well know where to find things. After a few visits, I got the store layout and merchandise offered pretty well figured out. But, on those occasions that I don't find it, then I will ask. What really screws me up is when two stores from the same franchise organize their stores differently. Crap, I have to start the search and seek process all over again.

Lou wrote:
"I am no expert on this but my thoughts seem to boil down to if there is no antenna, there is no drain, so the transmitter can set up the desired voltage with less current, and everyone is happy."

There is a 50-ohm coax r-f output in most cases. A wave has been generated and is traveling to the coax connector. Where it encounters an open-circuit, current is interrupted. Energy in the H-field has no place to go other than to the E-field, causing a voltage double. This is called the Ferranti Effect. Some transistors can`t take it.

Best regards, Richard Harrison, KB5WZI

Not quite true, Bill. I don't like to use the locking plugs and sockets
because they are so bloody expensive. The L6-20 is functionally equivalent
to the 6-20 which I recommended. Actually, the plug and receptacle we all
should be using is the 4-wire model, 14-20 P and R, (or the locking L14-20)
which has 4 pins and provides a separate ground and neutral. Since many of
the 240 powered units we use connect circuitry to the ground pin to support
some 120 volt function, this would then meet present code, which it now does
not, except that it continues to be grandfathered. Again, these plugs and
receptacles are 2 to 5 times as expensive as the 6-20 series.

"Does anyone have the recipe?"

Having an aversion to coil winding, I`ve bought dip oscillators and kits with pre-wound coils.

Good instructions for DIY dip meters are found in RSGB`s "Test Equipment for the Radio Amateur". It includes G3HBW`s dip oscillator using (7) two-terminal coils to cover 0.85 MHz to 150 MHz. For stability, the 9-volt battery is zener regulated to 6.8 volts. That seems unecessary and wasteful to me. My heathkit does very well without any regulation. This is no transmitter VFO, after all, and high stability is not needed or obtained even wiith regulation for most dip meter uses. I would leave out the regulator and see how that worked.

Best regards, Richard Harrison, KB5WZI

I realize that I left out the most important reason for using prewound coils is the calibrated dial this makes practical. The time saved to the builder by not having to fuss with calibration is substantial.

Thanks Richard, but there are only two coils -- the MFJ-259B has a digital readout. The two coils cover the frequency range of 1.8 to 170 Mhz. I suppose I could experiment, but if someone who has the coils knows the form size and approximate number of turns, it would sure save me a lot of cut and try -- and this is probably the best place to ask. I've built a few devices in the past where coil and cap had to match a degree of calibration -- thankfully we don't have to deal with that sort of stuff too much anymore. Thanks for trying to help though -- you might not have realized that the analyzer has a dip capability with the coils sold as an accessory. It just seems to me that to pay what will probably cost $30 Canadian is a lot for two coils which should be easy to approximate. If I wasn't so darned lazy (busy playing on the air or on the computer) I could have built them by now <grin>

You could get a coax fed magnetic mount antenna base and stick a 19"
piece of steel whip in it and trim it down until it matches.

I used a 1/4 whip with very good results and it's dirt cheep.

I'm sure there are better performing antennas out there, but it'll
cost you a bit more.

Any 1/2 wave CB antenna such as the antron 99 already is the same as a 1/2 wave J pole. A 1/2 wave is a 1/2 wave. The only way you can improve one is to add better decoupling. That is what the add on kit for the A99 is. Seems to me if building a 1/2 wave CB antenna it would be simpler to just use a 1/2 wave radiator and a gamma loop feed at the base. A 1/2 wave on CB is appx 17 ft, not 27 ft. The cushcraft AR-10 is an example of this method. A j pole on 11 meters could be kind of clumsy mechanically. No real need for all that extra metal. A gamma loop for CB is only about 11 inches dia, single turn. I make them out of copper tubing. Many of those 10-11 meter antennas as so cheap it's almost not worth making one. I don't think the AR-10 is too much. And you can use it as a base to make other verticals. MK

I have been noticing a fairly loud buzzing noise coming from the tops of two nearby power poles. This has devloped in the last two weeks, as the rains have really come to Seattle. No sparks or arcing visible, yet, but I do have intermittent S4 noise across most of 80, 40, and 20 that is consistent with faulty insulators or pole pig connections. I have never dealt with a power company on this issue before, so I seek advice on what to say when I call them. How should I phrase my complaint/concern/report? Should I mention being a ham and the received noise, or should I keep it to the audio noise heard on the street? Suggestions for strategy graciously accepted.

Quite right Mark

I guess the only argument for a JPole is that the matching section gives your aerial another 9' of height. The other argument is that if you also have it constructed as a cactus configuration for use on other bands, it will get your 2M band and the like, JPole section nice and high. You are right, if I was putting up a vertical on ten it would be a half wave!

In my couple of encounters with a power company regarding noise, I found them to be eager to fix the problem. They were glad to get my report, since it enabled them to fix it while it was just making noise and before it caused a power outage, which would have cost them real money. If you hear an audible noise, be sure and mention it, since it'll save them time and trouble tracking it down.

Its no wonder that it reminds you of a CB. The manufacturer, Ranger, made
their name by making 10 meter rigs that were set up to be easily modified
for CB ((just clip a wire I believe). With that simple modification, they
would cover the CB band and with the press of a button or two, the readout
would indicate channels instead of frequency. They were aimed at the
freebander.

Just call their regular trouble reporting noise and tell them they've
got a connection arcing. That pretty audiovisual show is wasting
their product, so they're usually pretty quick about handling it.
Just make sure you can describe exactly where the problem is at.

Best Kenwood Specialists!,

I Have a Cat interface (not the IF-10D) for my TS50s trx.
There are several programs but, none are using all TS50 commands (as far
as I know).

I'm a Visual Basic (6) programmer, and have a lot of experiance with
datacommunication.
I want to write my own program (and for other HAMs) specialy for the TS50
(window with
graphically the TS50 in it).
And i want to make a lot of the buttons to work.

I hope that you can send me some more info (ore where i can get it) about
the Cat commands.

On the moment i only have:
ID; IF; FA..; FB...; RX; TX; FNx;
SPx; MDx;

I look for commands for RIT, MEmory, AntennaTune, Power, Freq, Up, Down and
all other
buttons on the TS50.

I hope you can help me
Please respond to my Email adres.

Many thanks in advance,

Leo van der Kallen (PA3HFP)
Netherlands
Email : pa3hfp@amsat.org

3241. ground for verticle

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-03 11:46:15 UTC
From: Steve & Dawn Heckathorn <heck@kconline.com>
Message-ID: <9ufohkhnl1@nix2.kconline.com>
Source record: 153494

It seems to me I read in a ham magazine awhile back. That you can make a ground for a vertical antenna by using wire mesh or something like that instead of radials. Then putting your vertical in the center. Is anybody familiar with this?

3242. resonant frequency of dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-03 12:38:54 UTC
From: Jerry <wb0mbi@qsl.net>
Message-ID: <ynKO7.3562$Ej1.820791474@newssvr17.news.prodigy.com>
Source record: 153495

I have put up a 17m dipole. I have used EZNEC and dipole1 for various assumptions. I initially put up a 26.5 foot dipole and it was too long. It is now down to 26 feet. I still get a 2.3:1 SWR.

I am using an MFJ antenna bridge and I get a reading of 79+ ohms on that antenna. I am afraid to cut any more from that antenna. Since I am using a 50 ohm feeder a 1.5 SWR is about the lowest swr I can expect. The antenna is installed 16 feet high under less than ideal ground conditions. The instructions for the bridge say I should cut the antenna till I get a 50 ohm reading.

since I don t have a j reading I am insure how to proceed. I may cut further and get a higher resistance reading. Any ideas?

I was just kidding. Unfortunately I can't answer the question either.
Just a SWAG, I suspect if the transistor had zero components following
it, then theoretically your guess would be correct. But in practice you
have harmonic filters, metering and even the choked and bypassed Vcc
line and I suspect THEY would become the load in the absence of an
antenna.

I have NEVER purchased anything from Texas Towers, for the following reason: I travel quite a bit on business, and use the opportunity to visit Ham Retailers when in town, to see in person the quipment that i am interested in. As it turns out, i usally frequest cities where HRO is located. On a recent trip to Dallas, I stopped into Texas Tower to 'browse'. I found them to be rude, curt, and unwilling to spend time with me unless I was ready to drop down my cash on the spot. Now, I am looking at purchasing a new HF rig for the Base, as well as a multimode mobile, and am cosidering the IC756ProII, vs. FT1000DMk5, as well as the IC 706 vs.FT100D. Neither of these are impulse purchases, and I will not buy unless I compare hands on. The venfor that is the most helpful will get the business, and Texas Towers will never get it.

In Contrast, I have visited the HRO stores over the past year, and as a direct result of their courteous service, have purchased the FT817, VX5R, and VX1 from them. In addition, I has a similar problem, with my VX5R, a bad ground in the radio that surfaced within 30 days of getting it home. The folks at HRO in San Diego (Where I purchased it in store), overnighted me a replacement, while my return was crossing in the mail (even though it was technically out of the replacement window, and should have been sent back for repair).

I can't say enough for the folks at HRO, and will continue to shop there (and AES) as long as the service remains constant. Note: I have had the same courteous treatment at other HRO stores, so assume it is a consistent company attitude.

This hobby is by definition a 'word of mouth (or key)' business, and products live or die that way. So do Vendors!

Don't waste your time w/ the dip coils- it is the most insensitive
dipper I have ever seen.
Look for a Measurements #159 meter- they are way beyond the Millen's,
Heath etc.

Jerry,
Don't 'cut' anything off of the antenna. Instead,
fold the amount you would have cut off, back on to
it's self, give it a twist so that it stays put. If
you 'fold' too much, you can always lengthen the antenna
again.

Steve,
Sure, and it works fine. It's basically the same
thing as using radials. You do need to bond the mesh
or screen sections together, or to a common point.
Make the length of the mesh the same as the height of
the antenna, or just a bit longer, and it should work
just fine.
'Doc

Irv:

Living there in Calgary you well know, what those Chinooks can do! All
you'll have to do is wait a few hours, that 10 inches of snow will be gone,
and you can be out in the yard with shorts on! Plenty of chance to use that
"new" 259B. BTW... was it a ham who sold you the 259? What???

3251. Problems with High Sierra Installation

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-03 14:22:48 UTC
From: duty_mountain@hotmail.com
Message-ID: <e276dcad.0112030622.192ab2e5@posting.google.com>
Source record: 153504

I just completed installation of a HS-1500 on a '91 Cadillac Deville. Mechanically, all is secure, and the antenna moves up and down. It will in fact tune everything between 3.5 and about 29 MHz. However, the drive motor is eating fuses like candy, and the performance (subjective observation) is not what I had hoped for.

What might I look for as an answer? I thought of grounding, but it certainly seems well grounded. The mount is connected to the rear bumper and connected via about 10" of the supplied grounding cable directly to the frame of the vehicle. Total resistance between the frame and mount is about 0.3 ohms. All paint, coatings and similar insulating materials were scraped clear of the attachment points. Is there anything else I can test that would shed more light here? Power for the drive motor is taken from the power connector for the radio. The power cords are about 8 foot long, 8 gauge stranded wire fused on both positive and negative leads. They run directly to the car battery. The drive motor fuse is 3 amp, installed on the positive lead, just as directed in the instructions. The radio is grounded to the automobile frame through a 6 inch heavy strap to a seat mounting bolt.

Does anyone have any suggestions about how I can correct the fuse problem? Does the description suggest anything else that might be wrong?

Thanks for your help.

I second that. I have (2) Measurements #59 meters, bought at flea markets for about $40 each and wouldn`t part with either. They are very stable, being regulated with VR tubes. I have several Heath meters. I really loved assembling Heathkits. I use the Heath HD-1250 dip meter more than the others because it is so convenient. It is powered by a 9-volt battery, like the G3HBW dip oscillator in the RSGB book. The Heath works fine with no battery regulation and the battery lasts and lasts.

Best regards, Richard Harrison, KB5WZI

Hi.

I recently purchased a used MFJ-989B antenna tuner but it did
not come with a manual. I downloaded the MFJ-989C manual from
the MFJ web site, but it looks like the B and C vintages are
different enough that I need the B vintage manual.

Does anyone have an "electronic" or "soft" copy of the MFJ-989B
manual (or a hard copy that you can scan in) to E-mail to me?

I tried E-mailing MFJ to ask about this, but they did not
respond.

If you post a follow-up, I ask that you also please cc.
my E-mail address.

Here's what my HS-1500 manual says: "The positive supply lead must be fused for 5 amperes." Mine works fine with that specified 5 amp fuse. If your manual says 3 amps, they may have changed it and got it too low. My HS screwdriver has worked perfectly for many years using that 5 amp fuse. Try a 5 amp fuse and see what happens.

You didn't say what the gauge of the wire was from the radio/switch to the motor. I would start by putting an ammeter in series with one of the leads to the motor to see how much current it is drawing. I think stall current on my BB3 is about 2-amps. Run current is much less. You might just have a bad motor.

There's so many sources of RF noise generation by the power company
in my home town that it is a hopeless situation. However, there is
one thing I don't understand. I wear radio headphones when I ride
my bicycle. At one intersection, WTAW from College Station, 35 miles
away, gets really loud (6dB louder?). At other points all around that
intersection reception is normal. There is nothing unusual about the
location of that intersection and I assume there is some sort of
resonance. What could cause such a thing?

These are a disaster if you change connectors a lot. Stephens adaptor
has an extra rubber ring around it that prevents the adaptor from
wiggling and thus breaking off the HH side of the sma connector.

Hi Clint,
No, you're not really missing anything. My point wasn't that they weren't good antennas. They are. My point was that if you've a tri-band, what reasoning proceeds not mentioning a tri-band antenna with comparable gain figures to the dual band (besides the obvious benefits of lighter, flexible material).
I also realize that the tribander probably has a loading coil and, though the dualbander has similar gain, the dualbander probably isn't resonant.
But, I still pose the question (just for discussion and first hand views)
"How's the RD-98SMA do on 6m?"
73's

I used to be chief engineer for WTAW and still live in B-CS, as well as Bill Watkins, the ex-owner of it is still one of my best friends! Are you talking about the NEW frequency for WTAW or the old one! There are now two of 'them' more or less, the old 1150Khz one and a new one up, I think at 1620Khz. The old 1150Khz plant is still in the same location as it was and is still is, I think a 1Kw plant. The 'new' one is a 50Kw creature at a new site I think is North of Bryan. At this point, I've never been on the new site, nor actually do I even know where it is. It may be significantly out of town by many miles. Things happen, grin!

Funny you should ask the question about road intersection signal intensity bursts and WTAW! In the old location instance, it's a 'problem' which has plagued both WTAW and, to a lesser extent, the old KORA 1240Khz site as well for many, many years! I never fielded a remark at your distances, but can tell you of many made over in-town instances of this .. along a particular route!

The plant location site for the old 1150Khz site (and the 1240Khz site for the old KORA) is right by one of the Bryan, Texas primary power distribution lines. Give or take a few thousand volts, it is a 69KV primary feed circuit which runs basically East and West along both facility sites! For some reason, this 69KV circuit is and always has been terribly hot with coupled energy from primarily the WTAW 1150Khz signal, and to a lesser extent, the 1240Khz energy from the other station! As you pass(ed?) by the intersection of South College Ave. and Villa Maria Road, if you have/had a receiver with an S Meter on it, you notice a huge bump up in the signal. East down Villa Maria Road over by where it intersects with 29th street, you would see another big jump! That main 69KV line goes on out way past there and transects with an even bigger line system which focuses in a large transformer substation bin about two miles South down Road 158 that goes to

Huntsville, Texas. That same major line also proceeds Northwestward back toward Bryan and on out of town, more or less North toward Hearn, Texas.

If you worked at it, you could find these intense peaks all along this power circuit from WTAW .. miles and miles away from the site!

There was NEVER any way I or anyone else could ever get rid of this deal, but that was in the 1960-1970 or so range, yes 30-40 years ago and it has, to my knowledge, NEVER been solved!

It would be interesting if you would post the location and also if you would, if possible, just for curiosity's sake, take the time to see if you could pin it to a realtionship with a major power line source at or near that intersection. Regardless of whether it is on the 1150Khz siganl or the new 1620Khz one, it would be interesting, I think, for those reading here, to be able to confirm that!

If it is the new higher frequency, I'd be glad to talk to Ben and the crew over at the station and go by the new tower location! It would be fun to see exacly the same coupling deal there as plagued us for years at the old one!!

Many people do not realize how many miles away critically reasonant wires can be on these broadcast frequencies and still cause serious pattern disturbances! Another incident like this while Tony Nemec, now deceased, was chief for WTAW is worth telling! WTAW, in order to go full time, had to go to a directional array to protect other stations at night! So they did! Years passed. Then Tony got a complaint from the FCC about poor performance on WTAW in the Southeast section of College Station over by the Highway 6 bypass and out toward Iola ..

They went measuring the pattern, and sure enough, it WAS down out there! But how? Nothing had been done wrong, nor changed at the plant away from the intial design and proof! They puzzled over it and then, by chance, I think it was Tony who noticed that the signal out there was wavering up and down a tiny bit in strength! He thought that odd, as at a distance of about five miles from the plant, there really, even at night, should have been no skip effects!

Suddenly, as he was passing by the site of the construction of the then new Hilton Hotel, he noticed something!

The Texas Stork building erection crane had a generator hanging from the boom on the line like they usually do! It was really windy that night and this generator was swaying gently and slightly in the wind! As it swung, the signal was moving up and down in intensity!

The installation was reasonant at 1150Khz! I think a whole lot of people were dumbfounded at this one!

They huddled with the construction crew and found a crane angle which nulled the interference problem. Per Tony, they made a deal with the crew

to leave the crane parked at that quadrant angle unless they absolutely had to do something else for anticipated wind or whatever! The interference problem went away! To this day, it is my understanding that there is a measurable, but otherwise insignificant problem with the pattern over there behind the shadow zone of the Hilton as it stands! Ordinarily we see none of this in practice. But the effects, tiny as they may be, they are still there!

There are, so I am told, MANY cases of where these new cell phone towers have gone up even ten miles or so from AM broadcast plants without the proper pattern interference check work. A number of them have, per Bill Watkins, had to have pattern interference mitigation work done on them to get rid of the mess they caused! Bill worked for a time, I think doing survey work at some of this with Lawrence Behr on it, but I may be wrong about the exact nature of that work.

Now I wasn't personally involved in the deal just above. But on hearing all this it should raise your curiousity such that you might pry into this and give us some feedback! My bet is that enough of us here will read and follow along just to see what the outcome will be!

--> Sleep well; OS/2's still awake! ;)

Well glad to see I was not alone!!
I was in Dallas for a wedding and I was looking for a new Yaesu FT-840 a couple of years back, I called and got directions to the store. I drove about 45 min. to get there arriving around 3:15 in the afternoon. As I got out and approached the door, a guy came out the door locking it behind him. I asked him if they where open he said no we closed early today. I told him I called and got directions but that no one told me that they where closing or I would not have tried to drive up there. He never apoligized, or said anything really. I used to work at a pizza deliviery buisness, I was told from day one that if a customer calls in with a complaint the first words out of your mouth should be "I'm sorry, what can I do to make it right". Even if it was not your fault. 1 positive experience told to 10 people gets you on average 5 new customers, 1 bad experience will loose you 10 on average. Great customer service comes from the root word "Customer".

I have been a fan of the Hamstation in Evansville IN. I used to drive almost two and a Half hours from home to do buisness with them. Always willing to talk to you and help out. Support you local ham radio dealer, they keep the hobby going.

Surprisingly Yes, it was a ham -- but maybe the battery leak confounded him -- I'm not sure. I'm waiting for the first Chinook wind -- maybe as soon as tomorrow, then I'll go adjust a homebrew trap antenna (one trap at 7.1 mhz) for 80/40 meters. It's pretty close now, but why not have it where you want it instead of just close?

My theory is that he did not have a DC adaptor and didn't know how to clean the corrosion. I'm a retired tech and it didn't take me long to have it going! The cost of a new one up here is over $400 Canadian -- plus taxes! I figured it was worth a shot. My whole station is composed of flea market specials, most of which required repairs of one sort or another.
Last year was a real winner -- I picked up a Cushcraft R7 and an MFJ Loop. The loop had a dirty switch in the controller, and the R7 had a shorted trap. Each cost me $100!!! I ham on a shoestring, but get more signal per buck than most! Heck -- my tower is a 30 foot lodgepole pine, my rig is a Kenwood TS-520S, and, Oh yes -- my Bencher Paddle cost me $40 brand new in the box! They should call me 'Lucky', but instead, in recognition of the fact that I am fair and honest, they call me "Fairly Honest Irv"

Thanks for all the info guys. It goes against my grain as a hobbyist and technician to buy anything new. I already have an old MFJ-207 HF SWR Analyzer (flea market special) which is easily used as a dipper (easy conversion by adding on a coil, two resistors, and a capacitor, and one coax fitting), but because MFJ says the 259B can be used as a dipper, I at least intend to try. I do watch for stuff like dip meters, but haven't run across one yet. In time I will, hopefully.

Thanks again -- love this newsgroup!

marvin rosen wrote:

> is there a schematic or a site that will explain how to make an artificial
> ground?

Hi Marv,
Its as simple as a variable capacitor, a coil, and a meter or
lamp all in series. At resonance, the current through the ground line is at a
maximum (series resonance), the impedance of the ground line is at a minimim
(series resonance) and the lamp glows brightly. Then put switch across the
lamp to get the resistance of the lamp out of the circuit.

It's kind of like a tuner, but between the rig and the ground. At the
operating frequency the impedance of the circuit between rig and ground is
essentially zero. At least that's the way I see it.

Hope this helps.

"Should go out to a 1/4 diameter. I use radial wires."

That`s probably a typo. The RCA old guys who perfected radials and the ground-plane antenna used 1/2-wave diameter ground systems.

It is an imaginary point radiator whose radiation pattern is a
perfect sphere. It is useful for comparisons.

>What exactly might an "isotropic radiator" be?

Hi Chip,

The meaning of the words is sufficient to explain: a radiator that
emits the same (iso) in all directions (or turns - tropic). The net
result at a great distance is as though the source (isotropic antenna)
is a point in space illuminating or filling an ever-growing spherical
surface with power. In contrast, the simple dipole, at a great
distance, appears to fill a surface that looks like a sphere punched
in from opposite sides (suggestive of a donut).

The charm of this theoretical radiator is that if you hold that
uniform sphere image in mind while distorting it into the dipole
radiation surface; you then come to observe that like a balloon being
compressed, pressure forces other portions of the surface to expand.
When you stand back and compare the two surfaces you will find that
your dipole has more emphasis in one direction over the isotropic.

The net result is that when compared to the isotropic, the dipole
"reaches out" in preferred directions. Just as it has preferred
directions, it has those directions for which it compares "poorly" to
the isotropic. We can conveniently call these directions lobes and
nulls.

This is all good an well, but we could compare ANY two antennas with
this basis of logic. The point of the isotropic is that it presents
us with a characteristic minimal and maximal signal that are equal at
any point. If your hot antenna cannot achieve this (maximal) level of
signal in some preferred direction - your antenna is hot only because
it is radiating heat. If your selective beam cannot null out this
(minimal) level of a signal - you have a real serious problem with F/B
or side rejection.

Is it flat top or inverted vee?

Do you have an analyzer to see which frequency it is resonant on? I have a vectronics analyzer that is invaluable. Knowing which frequency it is resonant on is helpful. Use your tuner transmitting low power and turn the tuning knob to the frequency with the lowest swr...if the resonant frequency is higher than the target, lengthen the antenna. If lower, shorten the antenna.

While that dip adaptor works, it doesn't work nearly as well as a
regular dip meter will.

The circuit coupling is very low because the coil is not part of an
oscillating circuit, so you have to be right on top of the circuit you
are testing.

Althopugh some people will claim otherwise, there is NO SOLUTION to
that problem. You will find no matter what form of adaptor kit you
build or buy for use with an antenna analyzer, the system will be
several times less sensitive that a real grid dip meter.

All you need are simple plug in coils, the amount of turns and size
will vary with what you are testing. Any resistors or anything else
you might add outside of a pure simple plug-in coil will only decrease
sensitivity.

So you see, there is no formula. It is all cut and try, and the
optimum size and turns varies with the size of coil and the frequency
of the tuned corcuit you are dipping.

Hi Jerry,

Add another length of cable to your system and measure the SWR again.
If it is different for two lengths of cabling, you have common mode
problems and need to choke the feedpoint. If the SWR stays the same
try some of the other suggestions here. Common Mode can mask itself
as tuning problems, this check is quite simple to eliminate this as a
source of confusion.

3283. Intelligent Ideas for using Steel Roof?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-03 20:58:21 UTC
From: lbrty4us@aol.com
Message-ID: <205ef942.0112031258.28522d7f@posting.google.com>
Source record: 153436

Anyone actually done so in some useful fashion? Ground plane?
Radiating element? Other?

FWIW I have fed my lower house roof (it has a smaller upper one as
well) from the center of its eave at 9W on 75M matched at almost 1:1
through a tuner as if it were an endfed wire, and copied it quite a
few miles away. The roof is galv steel over plywood, 4/12
equal-pitched. Was doubly amazed as eave is only 8-9' off the ground.
Considering trying feeding much smaller upper roof (same pitch) &
using lower one as gndplane<silly>.

This also raises the issue of dealing with the effects of a steel roof
beneath a low-band vertical(?). But any metal up in the air is metal
up in the air - ther must be a way(s) to take good advantage of it.

I just experimented with crudely feeding a low steel roof (wood house)
that's eave is only 8' off the ground, on 80 with qrp-pwr AM, fed as
if it were a straight wire. It loaded much heavier than the dummy, I
got it down to about 1:1 & was amazed by the propagation. Books,
theory and software are great & important things - but the only way to
know how something will actually work is to do it in real life and
observe or measure the results.

lbrty4us,
I've tried loading a metal roof. It did work, but
the RFI problems that resulted would have to be heard
to be believed! Needless to say ~that~ antenna didn't
last too long. As suggested, your roof should make a
great groundplane for a vertical antenna, and putting
a dipole over it would definitely change it's loading
and/or radiation pattern. How, or how much? Who knows.

Should have said this before, just didn't think
about it.
If you support your dipole in the center, and
'droop' the ends a bit, you'll find that the input
impedance will drop to something closer to 50 ohms.
If your 'happy' with the length of the dipole, letting
it 'droop' into the 'correct' impedance, is probably
the easiest way to drop your SWR.

The input resistance at the upper end of a half-wavelength of wire grounded at the lower end is -

Ground connection resistance + 1/2 wire HF resistance + 73 ohms.

73 ohms is the wire's radiation resistance. No matter how good the ground connection may be, the input resistance can never be less than the radiation resistance. Is everyone happy with this high value? Does it matter very much?

Does that 73 ohms change if the half-wavelength wire isn't in "free space" on its way to ground ? In other words, if the grounded wire is snaking around the shack and into the basement and along the concrete etc., is it still 73 ohms ? I think that this is a rhetorical question, but I'm all ears.

3293. Tuning A3S

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-03 23:17:38 UTC
From: Edward Lewis <kq6dx@pacbell.net>
Message-ID: <gn0o0ucagfpadhfgp1n183t676ev2jps4h@4ax.com>
Source record: 153446

I put up a new Cushcraft A3S with the 40 meter kit. I tuned the antenna for the middle of the band and it is ok on 10 and 15 meters with an SWR of 2 or less through out the bands, But on 20 meters my lowest SWR is 1.2 at 13650.with 3+ from 14000 up, and 40 meters has its lowest SWR 1.2 at 7050 and 3+ from 7200 up. I think I need to shorten the space between the 15 and 20 meter traps to bring my SWR up in frequency on 20 and I will leave the 40 meter length as is. I hope this is ok as it is lots of work to lower and raise this antenna. Has anyone had any experience changing the factory dimensions on this antenna. will changing the length of the antenna after the 15 meter trap have any effect on the 10 and 15 meter bands I don't think it will. I put up my old A3S one time using the factory dimensions and it worked the first time but this is the second time i have had this new one up and it is still not right.

Hi Doc,

It would be quite common what with lead and connector resistance of
the garden variety digital multi-meters with a 200 Ohm range and 2000
count display.

In other words, the test equipment contributes more resistance than
the sample.

Hi everyone,

I am a former ham, WA9SVS (this was 1967) and I am thinking about getting back into it. My biggest concern is finding a very low profile antenna that will provide reasonable performance in the 40M novice and general frequencies. I would anticipate operating CW in the 7100 to 7150 range and SSB in the 7225 and 7300 range.

I appreciate any assistance.

Thanks

If the utility marks the poles with numbers, it will help them precisely
locate where the trouble is. Here in the northeast, every pole has
an ID tag with the pole number embossed on it.

Mention both the radio interference and that the arcing can be
heard. That is a sign things are degenerating rapidly.

I bow before the antenna masters asking their indulgence to draw upon the vast collective knowledge herein contained....

What's your favorite wire for homebrew antennas? #12, #14, larger, smaller? Insulated or not? Solid or stranded?

I've modelled out a rather interesting no tuner antenna for 10m - 40m that can be mast mounted and will take a minimum of space. When I build it I want to use the best components for the money.

I see LOTS of options and widely varying prices in the wire market. But I've not seen anywhere a simple statement as to what is the best wire for different purposes.

Obviously cost is an issue as I am homebrewing, so no recommendations for .9999 fine silver :-)

Thanks!

I have gone through 4 or 5 of Stephen's adapters over the last couple of years,
but the life span of his adapters is much better then the cheap adapters that
you can obtain elsewhere. I use the adapters every day in
all sorts of extreme environments, such as sitting in my van with my Icom R2 in my pocket.
Not a smart thing to do. Only one of the adapters failed for an unknown reason, as I was
changing
out antennas, but all of the other adapters failed because I tortured them. My whip
antennas also
wear out every few months.
The bottom line is that the adapters lost, the radio won.

I have a 259B with the coils, the "coils" were a complete waste of
twenty bucks. DON'T BOTHER! One of these days I'll glom an old Heath
or Millen crapper and tap into it with a freq counter to "get the
calibration right".

My favorite wire?

14 AWG stranded soft drawn copper (yes it will stretch a bit, where
Copperclad steel will not)

Copperclad steel tends to have "reel memory" (which I do not like).
However copperclad steel is useful if you dipole will be under tension.

My sources:

1. Home Depot, insulated 14 AWG stranded in 500 foot spools (choose your
insulation color)
Preferred choice, great to solder and insulation protects wire surface from
environment

2. The Wireman, 14 AWG, 7 strand, uninsulated (his # 541)
Second choice, use it when I may "tune the antenna" alot and do not wish to
strip insulation constantly.

Dave -

40 meter dipole is very easy to build and can be low profile.

Achieve low profile by insulation color on wire and insulators as well as
the size
of wire chosen for the antenna elements.

About 66 feet in total length, cut for 7.15 or 7.175 MHz for optimal
coverage in
your specified bandwidth.
http://home1.gte.net/kb7mmv/pageant.html

Shorter dipoles are also available:
http://www.qsl.net/g3pto/shortant.html

Some of the other web pages and links that I would have
provided are still down -- due to the AT&T and @Home break-up

3310. SIGMA 5 Vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-04 03:27:15 UTC
From: Ted Sloan <tedsloan@ntlworld.com>
Message-ID: <b%SO7.2293$P4.327157@news6-win.server.ntlworld.com>
Source record: 153442

I would like to hear from anyone who owns and uses a SIGMA 5 Vertical antenna.

I have read the Web pages relating to it and have seen some reviews written by a prospective retailer but have never come across comments by anyone actually using this aerial.

I would be interested in hearing
(a) Modes used.
(b) Power employed
(c) Actual results with respect to DX regualarly worked.

It is an expensive item and am wondering if it would be any better than my existing sloping, trapped vertical .

Jerry -

Reduce the feedpoint angle from 180 degrees (dipole) to about 120 degrees
(Inverted V) and you
should see an impedance drop (Z) on your MFJ. Also get your feedpoint to
be the highest point for the
antenna.

This should improved your overall SWR

3314. Re: Hamstick Antennas on 75M and 160M

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-04 03:42:21 UTC
From: Tony Bogusz <tony_b@ameritech.net>
Message-ID: <xCXO7.5498$Rw2.3986416@newssrv26.news.prodigy.com>
Source record: 153468

Thanks to all who replied.

The ProAM PHF160 is a 3/8"-24 mount antenna. It starts at the base with a mast about 3 1/2' long , going into a 12" long by 1 1/8" in diameter center loading coil and ending with an adjustable 3' stinger on top. (Yes, I know, a larger diameter coil would be more efficient.) Total length is about 8 1/2 to 9'.

I have it installed on a ball mount on the side of my van using a 1/4 turn quick disconnect adapter. It came resonated at the bottom of the band (1800KHz). It tuned easily to 1900KHz using my MFJ259, but only offered a 1.5:1 match at resonance. 600pF of shunt capacitance alligator-clipped between the ball and ground screws of the mount dropped the VSWR down to a little below 1.2:1 at resonance. (Good enough.) It's a hi-Q critter, giving 1.7:1 bandwidth of only about 6 or 7 KHz.

So how does it work?

With 100W on SSB tonight I worked into mid-Iowa, Indiana and southern Illinois (south of St. Louis). I wasn't really strong at their end, but with the reasonable noise levels tonight after dark the first 2 stations heard me quite well while I was driving home from work. (The Iowa station was about 300 miles away from me.) More power would have been nice, but the antenna is rated at only 250W maximum. As I indicated before, the antenna's loading coil is much thicker than the fiberglas mast of a 75 thru 6M hamstick. I believe this is why the 160M antenna seems to be more efficient than the 75M one with its 20" long by < 1/2" diameter integral coil.

Overall, I'm pleasantly surprised and satisfied with the performance. I will, however, probably have to use one strand monofiliament fishing line to a tie point on my roof rack to guy the antenna a bit. I found that freeway speeds built up enough wind resistance to rotate the ball mount about 10 degrees toward the rear of the van. The 75 to 6M hamsticks don't cause this to happen.

If you're looking to try 160M mobile this dark, cold winter season, I feel you can't beat this antenna for ease of installation and tune-up. At $69 it was a steal.

>Suggestions for strategy graciously accepted.

In dealings with my utility company, I get a better response
complaining about interference to my TV rather than to amateur radio.
They consider amateur radio a "weak signal" mode, thus susceptible to
weaker interference levels and thus harder to cure. Sometimes even
telling them which pole it was coming from didn't help. Telling them I
had sparklies on my TV screen and noise in the audio got a better
response.

I would think audible noise would get their attention even faster.

Try the http://radioworks.com/ site. They're pretty good about giving the pros and cons of various wires, support ropes, etcetera. The best wire really depends on your particular circumstances -- weather, wind, trees, etcetera.

Or, just go to Home Depot and get anything that looks like copper and throw it up and it will probably do fine :-)

Hi Doc,

I've been busy the last week or so and haven't been in here lately.
Basically, the 2" versions
that I build DO outperform the "skinny" ones. Just as an aside, I also use
a separate inductor
at the bottom instead of the torroidal matcher. It is much simpler and
easier to set up than the
torroid. Plus it is out in the open where you don't have to open P-boxes or
disassemble the
antenna to get at it--once you find the correct match at 75 meters, the
thing works on all bands
without changing anything. I found that the torroids sometimes give trouble
up on 10 meters AND
they also don't like power. With the inductor system and the form material,
you don't have to worry about ruining your coil.

Just vary the center point of the dipole a few inches. You can get any
match you want with a little trimming. It's too long now, so you will
want to cut a bit more. First, try folding a bit back on each end, one
end at a time. See which side makes the largest difference. On that
side, then cut a bit. Only an inch at a time. As you get close to the
frequency you want to get tuned to, you will have a certain feedpoint
impedance. Lets say it's not 50 ohms, but a little higher and you have
a 1.4:1 SWR. You can still get a perfect 1:1 match by adjusting the
center point. You will have to tinker with it and maybe add to one
side a bit , while taking off from the other. But you can get a
perfect match after enough diddling. Give me enough time, and I can
tune any dipole to 1:1 swr. Of course, signal wise it's a waste of
time, but as far as usable frequency range for a solid state rig it's
not if you need to stay under 2:1. Also, you might be better off not
using the bridge and just using your rigs SWR meter. I'm fully
convinced those things make an easy job hard unless you know exactly
how to deal with the numbers it gives you. I never use them myself.
They can be handy, but I've never needed one to tune an antenna. I've
seen them confuse some people to the point of being nearly totally
lost about something that should be very simple. I'm not saying you
are lost, but I'd take what you read with a grain of salt when
applying to real world tuning and trimming. At the end of the day,
it's the SWR to the rig that really matters. You can have a good SWR
and not always have a 50 ohm feedpoint impedance. MK

Not necessarily, Pete. I used to live along a long, busy power line run that generated horrible S9 + 40 dB interference and at night you could take a walk under any pole along that run and hear buzzing and sizzling noises. In the twenty years that I lived there nothing ever got any worse. The sizzling and arcing was always the same, year after year. Calls to the power company met with a willingness to help but almost a complete impotence when faced with the monumental complexity of this particular run.

Thats my source also. It helps that a home depot is within close
walking distance. :)
My main antennas are made with the #12 stranded insulated wire, and I
also use the #14. I'm getting to where I prefer the #14 for most
experimental/portable antennas as it's lighter and still very strong.
You will find after about 3-5 years it will shed it first clear skin
like a snake. But then the UV rays just start on the colored
insulation which will probably last quite a few more years. Then you
get to start over with fresh skinned uninsulated..:/ I prefer the
solid wire for winding coils although the stranded will work ok. The
price of wire at home depot is pretty cheap compared to buying
"antenna wire". You get 500 ft for about the same price as 210 ft of
rat shack #14 antenna wire for one example. "3 rolls of 70 ft" 500 ft
of #14 at home depot is about 19 bucks +- for copper prices, etc.
About 30 bucks for 500 ft of #12. #12 is so strong when I had a large
tree branch fall on a leg, it bent the mast over. The wire wouldn't
break. MK

Sounds like it's working fairly well. Maybe I'll hear you on there sometime. I'm usually in the 1880-1995 kc range for SSB. CW, I usually hang out in the low end about 1805-1820 range. I'll have to find me a long stick to make a 160m version from. Also, you can further improve yours with solid masts to put under it. Adding mast below the coil varies the resonant point only slightly compared to adding above the coil, but it improves the efficiency quite a bit. I keep a 3 ft mast to use under mine when I'm parked. "12 and 13 ft total depending on which antenna I use" The mast probably gives me another 3 db or so on 80m. About like doubling my power. If you add 3 ft below the coil, you probably only need to adjust an inch or two above the coil to tune to the same spot. MK

3326. Bruce array design

From: CA <123@456.com>
Message-ID: <3c0c8e13_2@news.sto.telegate.se>
Source record: 153328

I'm planning for a Bruce array for 10 MHz with 6 vertical "elements".
I have seen the formula 246/f for the principal sections (feet) and 110/f
for the tail sections (also feet).
As the tail sections are supposed to be Lambda/8, why not half the length of
the principal sections?
Is this related to the wire size?
I'd also like to hear other's experience with this antenna type.
Recommended height above ground? Any extra ground plane needed below the
array?
tnx

The problem with that approach is that you can get just about any answer
you want, depending on how you position the second wire relative to the
first.

David,
I think the 'best' wire to use for antennas is
one that will hold it's own weight with out undue
stretching, and what ever wire you happen to have
on hand. Usually, #14 will work for anything you
might have in mind. For the size to really make
a big difference, you would have to be dealing
with very high frequencies, or very long, unsupported
spans. Other than that, the 'best' is what'cha
have...

Those who are trying to tame a balky transmitter PA stage will be happy...

Heh, ...

That is, as long as they don't mind the radiation that happens to go along with that 73 Ohm radiation resistance.

But not all ground lines are 1/2 WL, in fact many are much shorter, in which case the "ground tuner" may be just fine and have little incidental radiation.

This is the exact same experience I had with AES in Orlando last month. I could barely get them to talk to me. I was ready to buy an antenna, but because of being ignored, and then treated rudely, I walked out. I like their catalog, but I will never buy from them.

Insulated wire changes the resonant halfwave formula from 468/F to about
454/F. Did you take that into account?

Source record: 153336

Scott, I would handle the issue this way: First, examine the exact wording of the agreement you signed (and any amendments the HOA made since you moved there). You may find a loophole big enough to drive a truck through.

Second, if that doesn't present a viable option, point out that the HOA can not prevent you from using your radio gear to the full legal power limit. If you have to install an antenna in your attic it may well expose your neighbors to excessive RFI and TVI. Point out that this is not going to be your fault and cite some technical documents from the FCC (see the OET documents on the FCC's web site).

Ask the HOA for permission to erect some discreet wire antennas outside. Point out that by placing these antennas outside, you can reduce RFI substantially and also increase efficiency, thus keeping the need for excessive power down (IE. you don't need to use a KW if you can get the antenna outside of your house).

Third, offer to disguise the antenna carefully so that it will not be recognizable. Ask to erect a flag pole. Offer to put it in your back-yard. Be sure to fly a flag on it.

You could also go covert and just call it a flag pole. What the HOA doesn't know won't hurt them.

Finally, if you can't do that, go mobile. If you're doomed to a lousy signal, you might as well make it mobile and have fun another way.

Good Luck. I've been there. I ended up going mobile. Now I live on a small farm with no covenants or restrictions. I only have to answer to my wife.

Greg,

I looked on the website for a copy of the manual, then sent email to support, but have not received a reply yet.But I already have a manual now, thanks to a fellow ham in England, who sent a pdf copy of the manual. I was looking for a downloadable version so I could go ahead with the assembly without having to wait for snailmail. I did offer to buy a copy in the email to Hustler, but that is unnecessary now.

So all is well, thanks. Already put it together.

AMEN!

My best working 80 meter antenna of all time was a section of copper flashing placed between a barn and a lean-to sometime in the early 1900's using an abandoned overhead cistern pump as a ground rod for the other lead. Operated from around 1970 to 1973 on this antenna.

Hi Roy,

More's the question in how the 73 Ohms is separated from the
measurement noise that easily eclipses this value.

3342. 50Hz Humm

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-04 18:48:45 UTC
From: richard@korma.freeserve.co.spamtrap.uk
Message-ID: <3c0d19af.35709026@news.freeserve.co.uk>
Source record: 153344

I have an IC-R8500 receiver with external white stick for VHF/UHF and 20m copper wire for HF. The 'white stick' is fed with RG213 coax and the wire connects to the radio via a Watson 'longwire balun' and RG58 coax.

Mainly after dark I start to suffer with a 50Hz hum on the received audio. It is most noticable down around 3 - 4 Mhz but can be heard on and off right up to around 130Mhz (especially bad on AM airband)

If I disconnect the VHF/UHF antenna then all I get is a normal hiss (no hum) on VHF with the squelch off but the hum is still there on HF frequencies. If I disconnect the HF antenna, then the HF audio is just a normal hiss (no hum) but the hum is evident at VHF frequencies. I kinda think this means the 50Hz is getting in via the antenna rather than the mains - am I right?

I've tried turning things off in the house but nothing seems to make a difference.

Can anyone offer any further advice?

Hi Mark,

I second your recommendation, but would press others to go one step
further with Agnitum Outpost Firewall
http://www.agnitum.com/
A free software firewall that is a slam-dunk to install, and
automatically refuses connections to advertising sources on web pages
(pages load a gazillion times faster without those banners). It also
reveals any internal process trying to sneak an internet connection
out of your 'puter.

You don't have to be a network admin to use this. Anytime something
unusual arises, the program will give you four choices to a novice
technical issue: always refuse, refuse once, allow once, always allow.
It's surprising how often microsoft daemons try to break through my
wall. It gives me great pleasure in pushing the button that amounts
to FO!

Hi Richard,

The significant clues I see are 50 Hz and the time relation to "mainly
after dark." However, you say nothing of your ground situation and
how your receiver is powered.

This sounds like a ground loop problem that is related to nearby heavy
domestic current consumption in the evening (electric heat?) and
sharing that load's mains circuit.

Move your radio (without doing anything else out of the ordinary). Is
there any change in the symptom's (unlikely, but could be conclusive)?

Move your radio's power connection (even if you need extension cords)
OR move the radio to a new outlet on a circuit different from the
original. Is there any change in the symptom's (50-50 here, which is
pretty good odds for so simple a test)?

Look at the quality of your ground for the Watson 'longwire balun.'
If ground makes your problem worse, you have a ground loop and a
problem with a mains circuit.

All of the above is predicated with the condition of "Humm." Other sounds like a buzz or rasping sound may be mains related, but only in the sense of conveying a small signal to you (rather than through the power fluctuation of a nearby heavy-user). Small pumps for aquariums or the aquarium heaters are notorious for being local sources of considerable noise and some of it may have the characteristic 50 Hz fundamental. For these generators, you may find that a portable radio also suffers and you can tote it around to pinpoint the source.

Richard,

Thanks for a very detailed reply, very interesting.

The supply is via a mains PSU which provides upto 20A at 12v dc to the
receiver. I have no earth/ground other than via the safety earth of
the mains socket that the PSU is plugged in to.

I will try the tests that you suggest and report back in the next day
or so.

Reg, G4FGQ wrote:
"73 ohms is the wire`s radiation resistance."

Yes, but if it doesn`t radiate, it doesn`t exhibit radiation resistance.

Radiation from a short ground lead is often trivial and even in a long lead radiation may be avoided. Long transmission lines can have trivial radiation.

So, run 1/2-wave of twinlead or ladder line between the output of the 50-ohm seeking radio and an earth-grounded coax connector at ground level. The twinlead doesn`t radiate. The radio`s impedance is repeated by the 1/2-wave of twinlead. Connect any length of coax needed to reach the "50-ohm" antenna from the ground-level coax connector. The radio is connected to earth through a 1/2-wavelength of wire and behaves as if it had a direct ground connection. This is a good lightning protection practice too.

This may not be convenient for band hopping but it should work for the 1/2-wave resonant frequency. If someone detects a flaw in this idea, I`m sure he will let us know.

Best regards, Richard Harrison, KB5WZI

This antenna is as new. Was up about 6 months total.
It has 17 elements and an n female connector. set up for
910 atv. $75.00 plus some shipping -- it will split in two
parts. If you have 900 atv in your area this is what you need.
73 KB8GRJ in Ohio this antenna is over $130 new.

3355. Texas Twister 2000 Screwdriver Antenna Any Good?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-04 22:39:41 UTC
From: dieselburner1@yahoo.com
Message-ID: <147ba4ae.0112041439.582c6847@posting.google.com>
Source record: 153358

I have been shopping for a good mobile antenna that can carry high power and will perform well. Does anybody have any suggestions and what do you know about the Texas Twister 2000?

A gamma match is unbalanced. If you are feeding the Yagi with balanced
line, the answer is yes.

Greg,

I have no complaints at all with Hustler or their support. I received an email from them a day and a half after sending a note, with an apology that the person who normally responds was out the day I sent a request. No problem with that at all. I was not complaining, just looking for another source, since they don't have manuals online for download. Sometimes manuals can be had from other than manufacturer sites, which is what happened.

It would be handy if Hustler did have downloadable pdf files of their manuals, as other companies do. That would likely be a timesaver to them as well as a service to all the used antenna buyers out there who get antennas without manuals or intstructions. (and like me, who can't wait to get that thing together and on the air) Or maybe that is not a common problem. I recently sold a radio that was missing the manual due to the moving company losing a couple of boxes. Forntunately, I was able to download a manual from the manufacturer and print it for the buyer.

I am happy with the antenna and happy with Hustler. And they copied me on your email to them, as well, so I had to write TWO emails to them today to say there is NO PROBLEM.

Life is good, 73,
Phil

Hi Dale,

I once used a 5BTV roof mounted when I was living in SC. I put up some radials strung out over the roof and it helped (almost none of which were in a straight line). And I can appreciate what your position may be, having been an apartment dweller for the last, oh, maybe 20+ years.

Anyway, I want to ask if maybe there is a way for you to lay the radials out such that they didn't have to extend onto your deck? Plus I once read an item that talked about using a metal screen mesh material under the antenna as the 'radials'. Seems it said that the need for a quarter wave 'length' in any one direction was eliminated if you could get several feet of this stuff radiating from around your antenna base.

Just an idea.... best of luck!

Mark

Source record: 153362

The problem with a metal roof is that it is not a monlith. The joints are not electrically bonded and certainly not RF bonded. If you try to feed the roof, corrosion causes the joints to act like tiny diodes throwing off all sorts of RFI. Or so I hear. I have never tried to load the roof directly or tie it into any kind of ground plane - so your experimentation is encouraged.

As for proximity effects, I have a GAP Titan mounted about 3 feet above a tin roof and a TGM mini beam about 15 feet above the same roof which is about 30 feet above the ground. I can't tell any ill effects from the metal roof as both antennas play as expected. I expect if the roof were lower (like on an 8 foot shed) it might couple with the ground causing who-knows-what to happen.

If you're using it from home mostly, try the groundplane on my page:
http://www.kd5nrh.net Just click on the first picture of it to go to
more pics and a description. If you want to put it on a roof, it's a
simple matter to attach the pvc to a vent pipe or whatever.

Yes. Folding back of the ends won't work too well if the wire is
insulated. In that case you will probably need to trim the wire. You
can fold it back, but being as the wire is not making a connection to
look as a single wire, the effect of folding back won't do too much.

I'll have to look at that one also. Also gibson research was supposed
to come out with a free firewall program. Not sure if they did or
not...I closed all my ports, etc a long time ago to keep probes from
getting into my box. Between the port probes/hackers, spam probes,

daemons, etc, etc, it's getting to be a hard world out there. If you are on a constant hookup like DSL etc, it can really be bad. I'd NEVER run a constant connection without a firewall. Being I'm still a dialup, I just manually closed my ports myself. There are loads of port crackers in europe for some reason. Most the people I know that run firewalls see attempts by them almost daily. The crackers run probe software that pings hundreds of puters an hour looking for an open box. They can go though a whole small country of puters in no time. MK

I have to admit I don't fully follow what you're proposing. But a transmission line won't radiate only if the currents on the two conductors are equal and opposite. With the connection I think you're proposing, if there's any other path to ground from the radio, this won't be the case, and the transmission line will radiate.

I just received my adapter from Stephen Gulyas and highly recommend
this product to anyone that wants to use antennas with BNC
connectors on any radio with SMA connectors on them.Not only is this
a great product but Stephen himself went above and beyond what one
would expect.I had made a mistake on my order to him and he went what
I consider to be way out of the way to help me out.
Steve gets my ***** award.
Mike Tesznar;
KC8RRM
They are much better than the adapters you can get at the local radio
shop.They stand up much better at the base of my HT because of the extra
support he puts on them.

Source record: 153371
Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna

I have multile radios that I'd like to put on the air. I have a Kenwood 6m as well as any of a choice of 2m or 2m+70cm radios. What I'd like to do is have a setup where both are connected to antennas and either or both can be used (independently or simultaneously). I only have one tower at present, and only a small yard. What are my options for putting up the least number of antennas to do what I want? I already own a 2m vertical and a 6m vertical as well as a couple of 2m quads. I'd like to get something horizontally polarized (SSB use) for 6m.

Thoughts?

Yup. More mast at the hi-current/low impedence feed point equals more
efficiency. It's just not too practical when going under bridges, if you get
the whole antenna too high. (LOL)

BTW, a single strand of Shakespeare clear-blue 20# test fishing line is
almost invisible when guying below the center coil housing to the roof rack
on the van. The ball mount never swiveled a single degree from the windload
at 75mph after doing this.

Look for me around 1900-1903KHz between 5 PM and 6 PM CST.

I don't know all the science behind it but I have a 40M and 80M inverted V off the same feed point. All I did to tune them was coil up the insulated wire equally on both ends of each antenna. I wound about 2 feet in a coil about 2 inches in diameter.

Roy, W7EL wrote:
"With the connection I think you are proposing, if there`s any other path to ground from the radio, this won`t be the case (balanced transmission line currents), and the transmission line will radiate."

Thank you Roy for pointing to a pitfall.

We can decouple unwanted parallel paths to the earth for r-f. A line-powered radio`s power supply can be isolated with an isolation transformer. Audio lines can use r-f chokes, so that the only substantial path to earth is through the antenna feedline. If balance problems arise in the r-f line itself, it can be balanced with r-f transformers and the earthing can be via center taps.

Another rub is the slight difference in velocities between the differential and common modes of propagation on the twinlead. This may slightly impair the avoidance of twinlead radiation, but ithe impairment is probably proportional to the differences in velocity which is small. The velocity factor of parallel-wire transmission lines such as these is about 80% to 90% that of free-space.

I would not expect a perfect ground connection via this "1/2-wave line section", but I would expect a reasonably good ground conductor which produced little radiation itself while the desired radiation from the unbalanced wire in the antenna system escaped normally.

Best regards, Richard Harrison, KB5WZI

Amateur Radio Antennas Made By Amateur Radio Operators
Our Mission Is To Bring You Quality VHF / UHF Antennas
At A Great Price
we feature a complete line of ready to use J-Antennas. The
frequencies we stock and that are not considered
special order are 1.2 ghtz, 70 cm, 1.25 meters, 2 meters/70cm, 2
meters/1.25 meters/70cm tri-band, 6 meters, and
10 meters.
We will make an antenna for any frequency from 10 meters to 2.4
Gigahertz to fill any need.(What is considered a
special order antenna) they would be antennas for sound systems,
marine or aircraft frequencies, commercial FM
frequencies, cell phone frequencies, any antenna not listed as
standard stock ham band antennas !
Where you need a "J" antenna, we will
help!
We have sold over 9000 antennas to date !
AS SEEN IN WORLDRADIO !
STARTED MAKING ANTENNAS ABOUT 1994
THESE ANTENNAS HAVE BEEN USED FOR THE PAST 4 SUPERBOWLS, NBC
STUDIOS IN
HOLLYWOOD, ALSO CBS AND ABC...USED AT LAST YEARS MTV MUSIC AWARDS,
ALSO THE TV
SHOW , DAYS OF OUR LIVES , AND THE ROSEY O'DONELL
SHOW.
WE MAKE THE "J" TYPE ANTENNA IN COPPER, AND A ROLL UP STEALTH
VERSION, WILL CUSTOM
TUNE A "J" ANTENNA FOR ANY FREQUENCY FROM 10 METERS TO 1.2
GIG.....
SEE US AT :

Been trimming insulated wire antennas for over 50 years by just twisting
the wire back around itself to shorten it. Has always worked well and been
effective.

A few hints:

First, it's ground plane, not plain

Second, it's PVC, Not PCV

You might scare customers away with typos and misspellings like that..

Aside from that, the site looks good, as do the antennas.

3383. High Sierra Installation - No More Problems

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-05 05:04:06 UTC
From: Adam Adkins <km5nNoSpam@earthlink.net>
Message-ID: <MPG.167764c0a34c1843989680@news.earthlink.net>
Source record: 153388

Sometimes, despite one's best intentions and most careful wording, innocent messages are taken the wrong way. Worse, the mistaken impression is passed on to others who have not seen the original message, and a whole host of problems crops up.

So, FOR THE RECORD:

I had a small problem with the installation of a High Sierra HS-1500 screwdriver antenna. My first course of action was to send a message to High Sierra. My second was to send the same message, VERBATIM to this newsgroup, which has always been a good source of information. It was never intended to be derogatory, nor (apparently) was it taken to be so by Jim Heath at High Sierra. Mr. Heath very quickly responded to my messages with cogent, clear suggestions and clarifications. He was at all times pleasant, courteous and professional. In fact, he thanked me for bringing to his attention that the amp draw at stall of the motor was slightly higher than the 3 amps listed in the instruction manual.
In the original message, I made the light-hearted statement that the drive motor was "eating fuses like candy." As I made clear to Mr. Heath yesterday, that was entirely due to the fuses I purchased for the project being mispackaged. The package clearly stated 3A fuses, but I didn't find out until I ran out and bought another package of 3A slow blow (at Mr. Heath's suggestion) that the manufacturer had packed 2A fuses in the 3A package. Mystery solved. No more problem.

Why am I making such an issue of this? Because some person, or persons, decided to take my comments and negatively twist them, and pass on the "modified" comments to Mr. Heath. He was understandably upset, after the quick and helpful responses to my initial query and follow-on emails. I am absolutely incensed that an honest, clearly worded request for assistance was maliciously twisted into something entirely different and whispered into a helpful gentleman's ear.
Normally I would not respond to such arrant foolish behavior, but apparently some have taken my comments to be a slap at High Sierra, their products and support. It was not meant to be, nor was it worded in such a way that any rational person could mistake it as such. Just to make sure that EVERYBODY UNDERSTANDS WHAT I AM SAYING, I WILL SHOUT.

I AM NOT DISPLEASED WITH HIGH SIERRA, OR THEIR PRODUCTS. I AM VERY HAPPY WITH THE LEVEL OF SUPPORT THE COMPANY HAS SHOWN, BY THE EFFORTS OF JIM HEATH, TO RECTIFY A PROBLEM THAT WAS NOT OF THEIR MAKING. THE PRODUCT IS WELL MADE, ROBUST AND IS PERFORMING EXACTLY AS ADVERTISED.

IS THAT ENTIRELY CLEAR???

A copy of this posting is being sent directly to Mr. Heath. Thank you, Jim, for your help. I do hope that this helps to lay to rest any ideas that I am not satisfied with the antenna, or your help. As I promised, I will follow up with you as I have a better idea (over time) of the performance of my new antenna installation.

To those who twisted my words, rest assured that I will not give you another chance. I have posted to this newsgroup on occasion for three years. I will not do so again.

> Scott.

Well, for quite a while "years", I thought it was pretty much
unneeded, but others seem to have had problems. So I'd have to say
yes. If you had a problem, I'd add a coax choke below the feedpoint.
But I have to say, I have two different yagi's up now, one for 6m, and
one for 2m, and neither has a choke below the feedpoint and both use
simple one sided gamma matches. I've never had a problem here, and
those two antennas as among my coldest ones as far as shack noise,
common mode problems etc. So just depends I think. Varying the
feedline length may have something to do with that. It sure woudn't
hurt to add a balun even if you had no problems noticed. MK

I would recommend using the quarter wave that that Joe has shown. All
it takes is an SO-239 (panel mount style), some #12 wire and some #4
fasteners. I made 3 of them, 2 meters & 220 & 440, all using brass
rod instead of wire and am very happy with the results. For outdoor
use, seal the 'backside' of the connector with some epoxy and don't
forget to weatherproof the coax connection.

Joe, I really liked how you did your portable mast!

The most important thing is to get the antenna up high and in the open
(above surrounding structures). Any antenna high and in the open will
outperform any antenna that is low or obstructed.

>sure he will let us know.
=======================

Flaw detected ! ;o)

A 3/4-wave vertical antenna grounded at its bottom end and fed at a
1/2-wavelength above ground, radiates exactly like a 3/4-wave
vertical. Same radiation pattern.

Furthermore, not surprisingly, the feedpoint input resistance at
the 1/2-wave point is the same as when fed at its base. It's about
52 ohms, SWR is a convenient 1.04 : 1

If the bottom 1/2-wave did not radiate, the feedpoint resistance
would be the usual 37 ohms of a 1/4-wave vertical.

The thickness of the insulation and the dielectric constant would have an influence on the resonant length. Is your 454/F formula an average for house wire used as an antenna, or something like that?

3391. Some questions about antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-05 06:22:42 UTC
From: lundaym@hotmail.com
Message-ID: <3fc504ad.0112042222.460c440e@posting.google.com>
Source record: 153395

The following questions have perturbed me for some time, and I would appreciate any help you could give.

1. I have an old(er) tube rig, a TS-520S. The thing works great after 22 years, but I have never understood how to use it with an antenna tuner. The 520S does have a PI-L network that can be used to match to an antenna with an impedance that is reasonably close to 75 ohms (as I recall from long-ago experience). But what if I wanted to run the rig to a large end-fed longwire, or a long horizontal center-fed loop of 100 feet? How do I use an antenna tuner in concert with the rig that has a PI-L? Do I tune the rig to a dummy load, then tune antenna to the rig? Any details appreciated, including IF I need a tuner or not?

2. In ref to question #1, I want to put the horizontal wire around my roof. Are there any impediments to using a center insluator and putting the center of the coax to one side and the braid to the other?

3. I've always been confused about the length of the coax. Sure, longer means more loss, but sometimes I want it to be a specific length (matching), other times I DON'T want it to be a certain resonant length. What about this scenario for antenna in #1?

4. If I wanted to do the horiz loop on #1, and I want it on the outside of my house, I obviously need to stay away from gutters. If I run it along the roof, halfway up the slope, do I need to worry about nails, etc? Assuming the wire will be covered in plastic.

5. In ref to #4, what's a good guide for the type of plastic-coated wire to use for this? Any design docs that someone can recommend?
TIA

Mark

Wes,

Congratulations on getting your license!

J-Pole is a great omni directional antenna (radiates equally in all directions)... cheap and pretty easy to build. They're generally made in two versions:

1) Copper Pipe (mount in your attic or outside)
http://www.tcars.org/elmer/jpole.html

2) Twin lead (tack up in a room or hang out your window)
http://hamgate.sunyerie.edu/races/antenna/pocket.htm

Here's a great 3 element directional beam antenna (you'll need acrobat reader for this one):
http://www.arrl.org/tis/info/pdf/9304054.pdf

I have made all 3 of these antennas and they all work great. Here's a picture of my J-Pole in action:
http://www.pa-sitrep.com/ham.htm#iam

I hope that helps and good luck.

3395. Re: Some questions about antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-05 09:44:33 UTC
From: Ralph Mowery <rmowery@dialpoint.net>
Message-ID: <3C0DEC81.6FB553B1@dialpoint.net>
Source record: 153398

1. To set up a rig with a tuner, tune the rig to the desired output into a dummy load with the antenna tuner out of the line or if it has a bypass switch , use that. Then put the tuner back in line and adjust the tuner for minimum swr . You should not have to adjust the rigs tuning tuil you make a change in frequency.

If the antenna has a swr of less than about 3:1 the tuning of the rig should handle that with out the need for the tuner.

2. While that is probably not the best arangement for an antenna, I don't see why you should not try that if it is the best you can do. YOu hear all kinds of things about a balum. While in theory they are 'needed' many antennas have been put up without them and they seem to do just fine. YOu might try coiling the coax in about 5 turns about 10 inches in diameter near the feed point of the antenna to get the same effect.

3. Usually the length of coax dies not mater except as to loss of signal and even an extra 25 feet or so will not be noticed especially below 20 mhz. Sometimes if the antenna is not resonate on the band in use teh coax can cause some odd feeding problems and will need to be lenghtened or shortened .

4. Don't worry about the nails .

5. Use any copper wire you want to. A good buy is one of the large spools at a home repair store like Home Depot.

Hi,

Although they are oriented for the professional audio world, not ham
radio, I would recommend you to look at the following tech notes:

Jensen System Troubleshooting Guide
http://www.jensen-transformers.com/an/ts_guide.pdf

Hum & Buzz in Unbalanced Interconnect Systems
http://www.jensen-transformers.com/an/an004.pdf

And, specially interesting, the device called "hummer" (Fig. 8) in
this one:

Wide Dynamic Range Analog Interfaces
http://www.jeffrowland.com/tectalk6.htm

You could use it to test whether the hum may be caused by ground leaks
trough the antenna connector. Be carefould though, make sure first
that the connections in your receiver can stand the few mA and/or
voltage introduced by that circuit. If you don't fully understand what
it does and why, don't do it.

NOTE: I am in NO way related to Jensen Transformers

Hi Mark,

I ran a TS 520 for many years with and without antenna tuners depending on
the type antenna being used.

Your assumption is correct load into a dummy load first the tune the antenna
with the antenna tuner. place an swr meter between the antenna tuner and
the rig it the tuner does not have one already in it. tune for lowest swr ,
this will normally be the best match.. but not always.
Then you may have to slightly retune the rig, but you should not see a great

difference if the tuner is set properly.. besure and tune the antenna tuner
with low power to start. not full output from the rig.

As for the Loop.. I'd feed it with open wire so it would work on all bands.

cheers,
73 dave KC1DI

>rod instead of wire and am very happy with the results.

Have you tried your 2m one on 440? Mine gets such good performance
(and 1.5:1 SWR across the 440 repeater inputs now that I've fiddled
with it a bit more) that I never bothered to build a second one.

>For outdoor
>use, seal the 'backside' of the connector with some epoxy and don't
>forget to weatherproof the coax connection.

I'm probably going to pot the connection between the SO-239 and the
radiator with hot glue as soon as I resolder it. (got banged around a
bit when I packed it up in a hurry for the SET) That should add both
some weatherproofing and some extra mechanical strength. I've seen
some of the coathanger models liberally coated with tool-dip.

>Joe, I really liked how you did your portable mast!

Thanks. Boredom is the real mother of invention, and PVC is the
father of low-stress structural invention :)
That was mostly inspired by a portable patio shade that a friend was
using; it had the two short and one long leg base, and could be made
quite stable with two easily assembled sandbags. That seemed more
logical than carrying around a larger, heavier base, since a couple
empty 10lb sacks are pretty portable.

Altogether, the whole antenna with mast, plus adapters, extra cables,
SWR meter, longwire and tuner for the SWL gear, either of my good SW
receivers, HT and charger, logbook, repeater guide, and a few extra
batteries for everything will fit in a large duffle bag.

As a bonus, it makes a great indoor TV antenna for those days when I
actually care what's on TV :)

Mine's a Yaesu YS-500 SWR & directional wattmeter. Listed range is
140-525MHz, power 4W-200W. About $50 from Texas Towers, IIRC, and
well worth it. It's a bit touchy on low-powered rigs though, so
unless you've got about 5W, you'll likely just have to tune for
minimum reflected power. Until you get one, though, cutting the
antenna to the length the handbook gives will give you a match for 2m
that's well within your HT's capabilities; those stock duckies
probably don't give a great SWR, either.

If anybody knows where AC3L's page went to, he's got plans for a good
little 2m two element beam there. I built one from scaps of PVC and
the remains of a TV antenna someone dumped near my old apartment. I
never did manage to get a particularly good SWR on 2m, but it made an
excellent directional scanner antenna, and for free, it was a great
deal :)

Peter, K1PO wrote:
"1/2-wave wire carrying current gotta radiate."

Not when that 1/2-wave wire is one of a pair, and the other wire is carrying an equal and opposite current everywhere along its length and the spacing between the wires is small. Then, the wire is part of a transmission line which has trivial radiation.

The purpose of using 1/2-wavelength is first, to repeat the impedance at each end at its opposite end, for the differential mode. This allows a 300-ohm twinlead to present a 50-ohm load to the radio when when a 50-ohm load is presented to the twinlead. The 1/2-wavelength line repeats whatever load is presented to it.

Second, the approximate 1/2-wavelength for the common-mode current will produce radiation, but the aim is to keep this small. The radio is applying its signal to the wires in a differential mode. If needed, center-tapped r-f transformers can be used to eliminate the common-mode and provide a ground for the radio.

A lead which repeats the impedance at its connection to earth essentially places that connection at its opposite end.

A lead which has no radiation has no radiation resistance.

Best regards, Richard Harrison, KB5WZI

Reg, G4FGQ wrote:
"Flaw detected!"

Reg seems to question how an antenna remote from the earth operates as a grounded antenna.

G.H. Brown, one of the old guys at RCA, showed how to do it with his development of the ground-plane antenna. Both halves of a dipole antenna are not needed for radiation. One is enough if you have somewhere for the current to go. In Brown`s case, it was the radials under the radiator. These radials don`t radiate because they are placed in offsetting directions and fed in the same phase.

The ground-plane antenna is often low enough for significant energy reflection from the earth so that an "image" is produced. It obviously works.

The impedance presented to the 1/2-wave twinlead is OK if 73 ohms, 50 ohms, 37 ohms, or some others higher, lower, or in-between, if the radio can handle the same impedance. The 1/2-wave section is only a "repeater".

Best regards, Richard Harrison, KB5WZI

Irv, VE6BP wrote:
"It`s as simple as a variable capacitor, a coil, and a meter or lamp all in series."

Irv`s description is right on-target. The meter or lamp informs you of maximum current which happens at resonance. At resonance, reactance is neutralized leaving only resistance in the wire to earth.

Some of the resistance may be radiation resistance which depends on wire length. At 80m, a few meters of ground wires may not produce significant radiation. At shorter wavelengths, radiation may be more significant from the same ground wires.

I proposed a way to avoid radiation from a ground wire which had to be long. I`ve worked at a medium-wave BC station with open-wire transmission lines. The ground for the station was the radial system. Line radiation was trivial, but at night to light your path along a transmission line all you needed was a bare fluorescent tube in one hand. Radiation wasn`t zero, but it was low enough that we met all directional array criteria and field strength at our monitoring points was within tolerance.

Perfection is unattainable, but good enough is possible.

Peter, K1PO write:
"He was asking about a single "ground wire" and an "artificial ground" tuner."

Marvin asked: Is there a schematic or a site that will explain how to make an artificial ground?

The series-resonant tuner is appropriate but allows a long ground wire to radiate significantly. This may be undesirable in some cases. I proposed a way to avoid radiation from the ground connection.

Reg, G4FGQ wrote:
"Flaw detected."

Reg may have been concerned that a 37-ohm load would not present a 50-ohm load to the radio via the parallel-wire line. The 300-ohm 1/2-wave line does little to exacerbate the problem. It just repeats whatever impedance is presented. A mis-match between the radio and antenna may need to be reconciled with or without the 1/2-wave line between the radio and earth.

Best regards, Richard Harrison, KB5WZI

The formula that I use is from the Yagi design program by DL6WU.
This formula matches up with the chart in the ARRL Antenna Book
and is for antennas with the elements mounted through the boom
and secured to the boom. For your case, elements secured to the top
of the boom, you should use 1/2 this amount.

The following equation describes this relationship for Boom Diameters
less than, or equal to, 0.055 Wavelength. This yields the percentage
of Boom Diameter which must be added to element lengths.

BC = 733 * BD_WL * (.055 - BD_WL) - 504 * BD_WL * (.03 - BD_WL)

Where: BC = Percent of Boom diameter which must be added to element
lengths.

BD_WL = Width of the Boom in Wavelenths

Yes, Henry Allen is the guy that builds the Texas Bugcatcher and he
also has a screwdriver called Texas Twister and a larger version named
Texas Twister 2000. Are there any others that have the TT2000 or have
seen it work that can comment on it's quality and performance? Thanks.

I have the TS-520S too, and love it.

> Do I tune the rig to a dummy load, then tune antenna to

For an end fed antenna you will need the tuner. Tune the 520S into a
dummy load, then put it through the tuner and tune the tuner for a good
SWR.

>
>
> 2. In ref to question #1, I want to put the horizontal wire around my

> putting the center of the coax to one side and the braid to the other?

No -- but how well it will work remains to be seen. You would
be better to feed the loop with twin lead to minimize losses, but it might
work well enough to suit your needs with coax. In my opinion, it's more
important to get a signal on the air first, and later worry about the type
of antenna or efficiency.

For multiband operation you would never find ONE length of coax to suit
all bands.

>

Try it -- it might work well. I ran a horizontal loop off a roof, running very close to the perimiter, and I used empty 35MM film cannisters for standoffs -- the base of each can held to the shingles with a dab of contact cement.

>
>
> 5. In ref to #4, what's a good guide for the type of plastic-coated
> wire to use for this? Any design docs that someone can recommend?

Any old wire will do -- insulated or otherwise.

>
> TIA

Lots of luck. There is so much science to antennas tht it is difficult to hit the ideal, but many hams work the world with far less than what you intend. Antennas are funny people -- until you try something you never know the outcome -- and in many cases you will be pleasantly surprised.

Source record: 153276

I must be losing it. Here I sit with a beautiful lady in the hot tub in the early morning hours with snow coming down all around, and we start talking about where the snow would melt on the longwire antenna when she fired the rig up on 10 meters this morning.

Hell of a good question...just for grins, let's postulate a random wire antenna at least a few wavelengths long at least a wavelength or so above the earth. Let's also postulate an antenna tuner at the base of that antenna that lets me dump all of my minisqueak 100 watts into that random wire.

I don't believe that the wire will heat uniformly. That is, there will be places on the wire that will get hotter than others from resistive loss in the wire.

But where? Power is the only thing that will heat the wire, so if we say it is at a voltage maximum, then the power loss will be E^2/R. Now E is going to be large, and R is going to be concomitantly small, so this seems to be the right place for heating to occur. Similarly at a current maximum, I^2*R is the equation, and although I^2 is large, R is at least decently large enough to heat up the works..

So how about it, gurus. Sit back in your hot tubs, pour another glass of champagne, and ponder upon the question.

Hi richard,
It seems to me there is another possibility which does not require stopping the current to stop radiation. That is laying another wire alongside which has equal and oppositely polarized current everywhere along its length. Make a transmission line out of the long ground wire. That is the condition of twinlead driven by a transmitter. Radiation from a balanced transmission line is negligible.

Best regards, Richard Harrison, KB5WZI

Thats the way to do it, and yes, you will probably need a tuner
for the long wire, AND a very good ground.

> 2. In ref to question #1, I want to put the horizontal wire around my
> roof. Are there any impediments to using a center insluator and
> putting the center of the coax to one side and the braid to the other?

Nope, that's the way to do it. Any impediments will probably
be mechanical. Be sure to weather proof the coax where the braid
is exposed.

> 3. I've always been confused about the length of the coax. Sure,
> longer means more loss, but sometimes I want it to be a specific
> length (matching), other times I DON'T want it to be a certain
> resonant length. What about this scenario for antenna in #1?

If the antenna's input impedance and the characteristic
impedance of the coax are the same (or close), the length
of the coax feedline doesn't make any difference. If you
want to use a 'tuned' feedline on a freq that your antenna
isn't 'matched' on, it shouldn't make any difference to the
antenna system on those freqs where the antenna is matched.
(That didn't come out very well, but I hope you see what I
meant to say.)

> 4. If I wanted to do the horiz loop on #1, and I want it on the
> outside of my house, I obviously need to stay away from gutters. If I
> run it along the roof, halfway up the slope, do I need to worry about
> nails, etc? Assuming the wire will be covered in plastic.

Not really. Since the antenna is 'near' the roof/nails/etc,
the input impedance will be affected, but if the antenna is
insulated as you describe, it ought to work okay. Be prepared
for lots of RFI... (since the antenna is nearer to the stuff
that's usually affected by RF)

> 5. In ref to #4, what's a good guide for the type of plastic-coated
> wire to use for this? Any design docs that someone can recommend?
> TIA

The 'best' kind of wire to use is the kind you happen to have
on hand. It isn't going to make much difference one way or the
other. If the wire will support it's own weight, it'll work.

That's always puzzled me a bit. Let's see. You put a coax choke at the base of a ground plane antenna to choke the current caused by mutual coupling between the antenna and feedline (which can be considerable). It converts an unbalanced (radiating) feedline into a balanced (unradiating) feedline. But it's an unun. Then you change the transmission line to twinlead. The balun does the same thing as before. The effect on the feedline is the same as before. But now it's a balun. (Or is it an unbal?) And if you have a dipole fed with twinlead, but the twinlead comes off the dipole at an angle, and you put the coax choke at the feedpoint for the same purpose, I suppose it's a balbal? Do I have this right? I want to make sure I have all these technical terms correct.

No problem. Start at the ends of the antenna. Moving inward, the current increases as the sine of the electrical distance (in degrees or radians) from the end. The heating is proportional to the square of the current. So the heat distribution is a sine-squared function. With a few minutes and a scientific calculator, you can easily plot this. The heating is always equal to I^2*R, regardless of the voltage, and the voltage is tricky to define along a single wire.

The temperature rise is another matter. The heat you apply will be conducted along the wire due to the excellent thermal conductivity of the wire. So the temperature profile will be a great deal flatter than the heat distribution. My one entanglement with a heat flow problem gives me great respect for their complexity, so I wouldn't begin to try even guessing at the shape of the temperature curve except to say that it'll be a very flattened version of the heat distribution. It'll be affected by wire insulation, wind, the nature of the air convection around the wire, and probably other factors.

Hi Richard,

Seems you are arguing a condition where one half of the transmission
line induces the necessary currents in the other half to create the
necessary fields.

But that other half would have to be loaded for a current to flow, and
if, in fact, all this were accomplished - there would be a lag in the
"bucking." This shift of phase brings us the same Common Mode issues
we started with.

Hi Doc,

A Choke appears as a two leaded coil device 1 billion times for every
application you are applying your meaning to. A more complete term
would be bi-filar choke when applied to decoupling feed lines from
feed points. The same bi-filar choke as constructed in BalUns, with
your application being physically larger.

Source record: 153291

you need an antenna tuner and SWR meter.
turn loading capacitor on rig to max capacitance (least loading)
ON A QUIET FREQUENCY WITH VERY LITTLE DRIVE; turn tuning capacitor to dip
of final cathode current. Ic
adjust antenna tuner for min swr on the rig-to-tuner coax.
No longer touch ant. tuner
reduce loading capacitance a step at a time and re-dipping each time until
the tuned Ic dip is about 85% of max. when undipped. Do all this in 5 secs
then cool off for five secs before continuing.
Tweak all at full drive.

Never mind what the book says.....above has been how to do it since 1949
in my own experience.

Bryan

The loop length starts at the ant. tuner socket , up the coax, round the
loop and back down the coax. . 270 feet will do 3.5 mHz and higher if the
coax is not too long

Plastic gutter is nice! Forget the nails.

Any Insulated wire will do but weatherproof the place where connections are
made.

If you know none of this are SURE you should use a transmitter?

As I understand it from, "Building and Using Baluns and Ununs", by Jerry Sevick, a coax transmission line is an unbalanced, i.e. shielded asymmetrical transmission line and ladder-line is a balanced, i.e. unshielded symmetrical transmission line.

First, Lenz`s law is invioable, but we don`t need to investigate transmission line mechanics to know parallel-wire lines transmit energy with trivial line radiation. Cecil would be using coax were it not so. I`ve operated many miles of 600-ohm line carrying many hundreds of h-f kilowatts with trivial line radiation.

In my proposal the twinlead has a transmitter on one end and a real load on the other. line radiation should be small.

Hi Dale,

I once used a 5BTV roof mounted when I was living in SC. I put up some radials strung out over the roof and it helped (almost none of which were in a straight line). And I can appreciate what your position may be, having been an apartment dweller for the last, oh, maybe 20+ years.

Anyway, I want to ask if maybe there is a way for you to lay the radials out such that they didn't have to extend onto your deck? Plus I once read an item that talked about using a metal screen mesh material under the antenna as the 'radials'. Seems it said that the need for a quarter wave 'length' in any one direction was eliminated if you could get several feet of this stuff radiating from around your antenna base.

Just an idea.... best of luck!

Now hold on thar! LOL!

While I make a competitive antenna called the Carolina Cyclone II, I happen to know Henry Allen--I've met him a number of times at local hamfests. Henry is an honest, Christian man who makes a good product. Indeed, the quick disconnects he sells come from K4EDK from Lincoln-ton, NC--also a good friend of mine. I use these on all my personal mobile antennas, and keep several around for testing antennas.

Henry tells me he is having trouble supplying the Texas Twisters right now because the supplier he uses has lost interest(?) or something. But, IF you can get the Texas Twister 2000, it IS a good product. It's just that they are sort of expensive.

I am using the BB Quad and can only give some performance reports -but not a direct comparison with the Gem Quad.
However, while the Gem Quad does not have the boom it still has a large foot print since the spreaders are set up to angle forward (and back) to achieve the effect of a boom for the spacing.
The BB Quad has a turning radius of only 7 ft which is very short indeed and one of the features I like. I had it recently down from my roof mount (reshingling) and it took me only 2 hours to put it back up (including the tower with mast and rotor).
As to performance: from my location (Toronto area) I have worke the world with 100 wtts (Australia, Asia, Africa and Europe). Compared to a R5vertical usually s3 higher on receive (actually probably better since lower noise levels are there), on send I compete well with other beams including quads - this for 15 and 10 meters. On 20 m performance is about s2 over the vertical with clear reduction at 90 and 180 degrees.
Note: I use RG58U cable with a choke close to the common feed point - the automatic antenna tuner at the rig handles the rest.

If it is a quarter wave antenna, and I think the Hustlers are, it really needs a counterpoise. Is the deck cement or a wooden deck around the pool? If it is a wood deck, can you tack the radials UNDER the deck surface, out of sight, out of mind?

If the parallel-wire line is troubled by imbalance, it may be balanced with baluns. The center-tapped variety allows connecting the center-tap on the balanced side with the ground end of the unbalanced side. If imbalance persists, it may be because one of the two conductors suffers more exposure to its environment than the other. In this case, it has been found helpful to improve balance by simply twisting the twinlead every few inches. That is why twisted-pair audio lines are twisted. It is the reason open-wire phone lines have occasional wire transpositions, etc. This is "old hat".

Now that we have had a good vigorous discourse on the artificial ground, let me raise another point:

It seems that all discussion thus far has homed in on series-resonating a single conductor of some length, the far end of which is attached to some version of "earth ground" and the near end of which is attached, via the tuner, to the "ground" point of the station. Richard Harrison posited an innovative approach using a section of transmission line rather than a single wire.

I seem to recall that the tuner, at least the MFJ version, can be used equally well to resonate a wire of some length which is floating at the far end, in the manner of the non-resonant "driven ground."

This approach avoids the use of a separate 1/4-wave wire for each band. It does nothing to (a) prevent the far end from attaining a maximum r-f voltage and (b) radiating.

If the sole purpose of the grounding exercise is to place the "station r-f ground" at zero-volts r-f, then it seems to me that using the tuner with a single convenient length of wire connected only at the tuner end would achieve that goal with much less trouble.

Comments?

Hi,
Thank you all for your ideas. As i recall this thread was originally about someone asking how the antenna works with or without radials. I have chosen not to put the radials on due to the location of the antenna and being that it is temporary its not worth worring about for me. As the manufacturer states it works either way, of course we all know its better with radials.
In my original post there was mention of my SB-200 amp to help the antenna performance where I was accused of adding to the QRM. My second post addressed that.

Soon it will be a moot point due to the tower and A3S yagi going up. (one of the reasons for not bothering with the radials).
Now I will really be able to add to the QRM
with the SB-220 and Johnson Thunderbolt or Heathkit Warrior for AM.

ZoneAlarm from Zonelabs.com has a free version that seems to work
well. I was amazed at all the attempts to access my computer that it
discovered when I first installed it.

> effective.

It does fine with uninsulated wire, but with insulated you don't get
the effect of actually having a wire to wire contact, which makes the
uninsulated act as a single wire. When you do this with insulated
wire, you don't have the direct contact, and will have to "turn back"
a much larger length of wire in order to move the same amount as with
stripped wire. Once you get to a certain point, it almost wants to act
like a form of an end loading coil,because you have to use so many
wraps and there is no direct connection. With the insulated wire, I
can fold back a bit to do a "what if", but I usually end up trimming
the wire, unless the amount folded back is small. With uninsulated, I
usually don't bother trimming the wire. I just leave it as is to be
able to return to the longer length someday if needed. I used to
switch for 75 fone to 80 cw in this manner. I'd go out in the backyard
and let out the "wrapped wire end" When I went back to 75, I'd wrap it
back up. Just as a guess, I'd say comparing uninsulated to insulated,
if you wrapped the ends of a 10m dipole back to 4 ft each, it should
tune 5m pretty close. If you did this with 4 ft of insulated wire, I'd
be guessing it would tune about 7-8 meters. The wrapped back ends of
the insulated add more length being they don't make a direct connect
and act as a single wire. MK

I'd go the 1:1. Your match may be ok depending on the spacing. I'd use
a coax section to match if needed. I've seen some use gamma matches on
those. MK

Hi Doc,

A nit-picker would point out that it need not be coaxial. Either coax
or twin lead works for BalUns and UnUns.

I sometimes wonder what the folks who started the use of PVC for
plumbing would think when they see the multitude of uses for it.
Perhaps the US Plastics Association (that might not be the right name,
but there is a trade group for plastics manufacturers) should sponsor
some sort of 'contest' for the wierdest use of their product.

Yes, an excellent approach for emergency communicators also: it would easily be packed into your vehicle and always be ready for use. You might consider taking a little time and writing it up for QST - could make a few $$ also.

George, W5YR wrote:
"If the sole purpose of the grounding excercise is to place the "station r-f ground" at zero-volts r-f, then it seems to me that using the tuner with a single convenient length of wire connected only at the tuner end would achieve that goal with much less trouble."

Agreed. George is the first I`ve seen to question the goal of the grounding exercise. The problem seems to be an operating position significantly removed from the earth, or maybe it is the result of that position.

An artificial ground may not be the best solution to the problem. A balanced antenna system that doesn`t need a good r-f ground for good performance may be the solution.

To use a grounded antenna system, all or parts of the radio system may be located at ground level and controlled from the operating position if the FCC rules currently allow amateurs to do so.

If more of the options are examined, I expect a solution better than the artificial ground may be found. The Astros are now playing on real turf and not on artificial "Astro Turf".

An r-f ammeter or lamp to indicate maximum current as a feature of an artificial ground may indicate that maximum current is its goal. Tuning elsewhere may be able to achieve the same goal.

If an artificial ground is intended to reduce stray r-f in the shack, the effects of stray r-f may be avoided by bonding all conductors within the shack. This should bring them to nearly the same potential regardless of what this potential may be with respect to the earth. There is not much potential for injury or damage from r-f where everything is at the same potential.

George has alluded to the right questions.

Best regards, Richard Harrison, KB5WZI

Actually here I always had the best results using 5/8 GP's on 10m.
Quite a noticable difference on ground wave. But the 1/2 w the next
best thing. Also I don't use 1/4 wave radials with 5/8 GP's. I use
either 3/4 or 5/8 wave. 5/8 radials at a steep angle give the most
gain. The 5/8 set up like that will outdo the 1/2 by a noticable
amount. Here, was an average of 1.5 S units on an average radios meter
working ground wave 30 miles apart to another vertical.
You can see a few examples I modeled at
http://web.wt.net/~nm5k/acompari.htm .
When testing in the real world at appx 36 ft heights, even the 5/8
with 3/4 radials beat the 1/2 wave that had a decoupling section. "A
set of radials grounded to the coax shield, 1/4 wl down from the
feedpoint". The 5/8 with 3/4 radials sloped gives almost the exact
textbook gain for a 5/8 vertical. I consider this:
http://web.wt.net/~nm5k/58dual1.htm as about the best you can do with
a single element radiator and radials. But it's almost a dual 5/8
collinear in function. Compare it's pattern to the 1/2 wl. Makes the
1/2 look a little sad..:(MK

Tried an inverted L for 40m, but it wasn't particularly succesful, so
I would like a delta.loop instead. Wonder if dimensions are important
for performance? 8+8+8m seems possible here, I do not care about
impedance and wonder if it has lower efficiency when not in
'ressonance' ?
Is the gain higher on 30m than 40m band?

Remote Control Door Lock Receiver Replacement
Removal Procedure
1. Remove the instrument panel (IP) top cover. Refer to Trim Pad
Replacement - IP Upper in Instrument Panel, Gages and Console.
2. Remove the module. Unsnap the 2 lock arms.
3. Disconnect the electrical connector.

Installation Procedure
1. Connect the electrical connector.
2. Install the module starting with the large tang-tilt. Snap the 2
lock arms into the square holes.
3. Install the instrument panel (IP) top cover. Refer to Trim Pad
Replacement - IP Upper in Instrument Panel, Gages and Console.

I haven t tried cutting it to 456/18.11 yet. This is not house wiring. The insulation is not as thick as in house wiring. I bought it in a 500 foot section for $15. I suppose I should have used bare wire, but wanted to keep the dipole more discreet. Have tried drooping the center, but that raised the swr. I am looking into an inverted v. SWR seems to vary from day to day. I am using a 25 ' section of rg8-x now and that lowered swr considerably. I wonder about the quality of this 8x stuff. According to specs a very lossy line and the copper outer braid is very meager. Anyway it is interesting to try all these things and I thank everybody for their input. Keep on inputting. Thanks.

Hello, from Plano.

I was in Texas Towers just yesterday, and took a friend with me who just passed his Tech, and we both felt like we had done something wrong by stepping inside their business. That killed the excitement of a new license in a hurry.

I've been to TT a dozen times in the three years I've lived here. I can't say I've ever had a pleasurable experience. I guess I keep thinking it will change.

73,

Jeff - KB4YKQ

CAM, W5DXP wrote:
"Are you saying that we can get out of phase currents in our ground wires?"

I don`t know how to interpret that question. I did not mean to imply we were balancing out currents at all spots on an r-f line. Waves traveling in opposite directions produce SWRs.

A wave traveling on a parallel-wire line away from a generator has a voltage between the wires which travels the wires at the wave velocity.

In r-f lines with air dielectric the velocity of the wave is almost the free-space velocity. In lines such as twinlead and ladder line the wave velocity is about 80% to 90% of the free-space velocity. This high velocity allows us to use a length of line which approximates a resonant length for both modes of propagation, differential and common.

I was saying that transmission lines can be simultaneously used as resonant circuits and as conveyances for a signal. Though this is a newsgroup, I didn`t think I was reporting news.

Best regards, Richard Harrison, KB5WZI

Hmm, there's no way all that hot rf is bleeding through the insulation to form a
"single" wire where it's wrapped together?

I posted a negative review about a mobile antenna on eham.net. It never appeared. Now I see that they are selling that very antenna that fell apart. In fact, as I read reviews of other mobile antennas, I saw their advertisement pasted all over the other products. Eham is now a store! They're pushing their products. Ehams is no longer the place for honest reviews. It would be like the ARRL and QST selling a particular antenna and giving it only great reviews in the magazine. I don't trust eham anymore.

As I said, I haven't been following the thread. What I am asking is:
If a transmission line is used for a ground wire, is it possible to
make the grounding currents mostly out of phase on the two wires
in order to avoid radiation?

Same experience here too when I was visiting Texas Towers in the DFW area a few years ago. Hell... if they don't want people visiting them, why not lock the door?

I have seen reviews that I have previously posted "disappear".

The reason given, to my inquiry, was that eHam wanted "recent" reviews.
This argument did not "hold water". eHam does have a disclaimer that they
can
"edit" or "delete" as they please.

I have since provided few reviews of products, since they will edit as they
wish.

Depends on what band you're on and what you're trying to do...

I have had difficulty putting a good signal on the air on 40 and 75
meters a ham-stick on my old hatchback. It's not easy to mount a
bugcatcher on a small car so that it stays attached at highway speeds.
I have an S10 pickup truck now, so my opinion may change as soon as I
install my TS-50 in the truck.

But you're right about running the higher bands from a car. I like
playing with 10 Meter FM and SSB mobile. One of these days, I'll get
a 377 sign-off so that I do this from my airplane!

I'll be on the air again when the new truck smell wears off :-)

Source record: 153247

The review that I posted several days ago was about the N7LYY Mel Woody screwdriver antenna. After a year of use, fingerstock has broken and the main coil was warped. Since Eham now is now a retailer for this antenna, they have deleted my review. Sales are more important to Eham than honesty. How can a site that claims to be a place for review also sell products? They are dishonest and biased, plain and simple!

3495. Re: Eham is dishonest

I recently posted a second review on the ClearSpeech Base Unit DSP noise filter. It was in rebuttal to another reviewer's remarks. I started the review with " I can't agree with <callsign>" and then went on with a civil review.

The next day I saw the first line where I stated I "disagreed" had been removed....but the rest of the review was left intact...I felt that was censorship but what can a guy do?

CAM, W5DXP wrote:
"If a transmission line is used for a ground wire, is it possible to make the grounding currents mostly out of phase in order to avoid radiation?"

Good question, and most things are possible but I didn`t include anything to avoid radiation caused by common-mode current on a parallel-wire line.

Stray r-f as a common-mode current would produce radiation from the transmission line used as a ground wire. Reg is probably right. If the wire can radiate it has a radiation resistance. At the resonant 1/2-wave frequency, we have eliminated the reactance, but the radiation resistance is still there. As George said, you might just as well use a series tuned circuit which is simpler.

There is a difference it seems to me. The series tuned circuit carries the entire antenna current. The balanced parallel transmission line carries the antenna current in the differential mode which does not cause radiation, and only stray r-f causes radiation.

Best regards, Richard Harrison, KB5WZI

I am looking for plans for the Arrow 2 meter 4 element beam. I am told that a project was published in 73 magazine in 1992.

If anyone has a copy of this article or knows where plans are available, I would appreciate it!

PS - any other Arrow plans or measured drawings would be appreciated also!

Thanks

Dave - KB8VJD

3499. Effects of wood on indoor antennas?

Newsgroup: rec.radio.amateur.antenna

Does mounting an indoor antenna (like on a rafter) have any effect on the tuning or performance of the antenna? I've heard somewhere that it increases the capacitance and therefore decreases the performance of the antenna. Is this true? I'm guessing the antenna's best performance is going to happen where the elements are clear of any obstructions, but maybe wood is "invisible" to RF...?

Aww shucks, there go my slippery fingers again. I'm hitting the send key a bit too fast these days.

>Outbackers?
>
> GDRFC!

It hardly matters. A shrunken 40 or 80 meter antenna just ain't gonna work all that well on the lower frequencies unless you have some truly impressive loading coils...

>I always wanted to try Aero Mobile back when I spent a lot of time in
>Beech Baron's, but never .. sigh .. got to do it. Back in the 60's and
>70's there wern't any such things as these tiny light weight HF pocket

I was planning to restore our ADF sense antenna and set up an autotuner to work with it.

But first, I need to be able to fly VFR from my home base. It's those stupid TFRs around DCA that are stopping all but IFR departures and training flights out of my home base.

Sigh. I just don't get it. Airliners were the problem and they're flying almost exactly as they did before. General Aviation aircraft were not involved in recent events and yet our fearless leaders intend to protect us from these "dangerous" aircraft which can't do any more damage than a compact car. I'd write to the NSC if I thought somebody would read my mail, but they aren't. Anthrax. What sad times we live in...

So what? Why does all that force them to be rude?...
The few times I've walked in there, they weren't exactly "manning the
phones"..
They were sitting in the back (of the showroom) talking to each other,
reading mags, or whatever.. Not taking phone-orders, or anything else which
they'd be loosing $$ on by taking the time to wait on me properly...

Dave- why not go straight to the proper source?- He puts almost all the
data you need on his site.
try:
http://hometown.aol.com/Arrow146/index.html

I made one from the 73 article, but, considering the problem of getting
the right material, he sells them for a very reasonable price.

Source record: 153260

Jan-Martin,
Dimensions are important, but not critical. Naturally, performance
on the antenna's primary frequency will improve if the loop is resonant,
but on other frequencies/bands performance isn't going to be affected
to any great extent.
Concerning efficiency of a loop, the shape also makes a difference.
The larger the area enclosed inside the loop, the greater the
efficiency.
That would means that a circle is 'better' than a rectangle, which is
'better' than a triangular shape. This difference in efficincy is
small,
though, so you may or may not notice it.
If a loop is made for 40 meters, it will have very little, if any,
gain on 30 meters and in fact may have less. Antenna 'gain' is a
function
of the antenna's radiation pattern (antennas don't 'make' gain, only
reshape the pattern in particular directions). The radiation pattern
changes when changes in frequency occur, so if the pattern changes in
such a way that is beneficial to the stations you want to hear, all
well and good. If not, then not so 'well and good'. Modeling the loop
would give you a very rough idea of it's behavior. It is worth doing,
but the 'models' seldom are the same as in the 'real world'. It's very
difficult to include all the surrounding objects, which will affect the
radiation pattern, in a computer model.
I think you might benefit from changing from an inverted "L" to a
loop. Theres no way of telling how much of a benefit you may get, but
loops are fun to play with! Good luck.

Scott,
Like you, i was faced with the dilemma about the legality stuff.
Though i live in a single family detached home and have no
restrictive covenants, i got onto the homeowners assoc board.
I am one of the board of directors. After getting on the board,
i found that each of the other one got onboard for specific personal reasons :)

You might be able to work from the inside after you get on
the board. After you are on the board, your neighbours complaints get to your
ears
first. Yes, with you polishing it up with your board buddies :)

Also watch out for those attic dipoles etc. Check the safe radiation power
levels.
Never compromise the health of your family/neighbours.

Also the mobile is an attractive option.

Good luck

3512. Cushcraft A4 Trap Problem

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-06 21:29:29 UTC
From: Kenneth Fattmann <na0y@worldnet.att.net>
Message-ID: <ZqRP7.212402$3d2.9561790@bgtnsc06-news.ops.worldnet.att.net>
Source record: 153265

A friend of mine put up a used A4 by Cushcraft. Tha antenna came on line on 20 meters with about 200 watts from his Yaesu FT 1000D. In justa short time period th SWR on 20 meters jumped to just under 5 to 1. The antenna is now resonate at about 14550. The 15 meter is even worse. The antenna gain is way down on 15 as background noise is gone. The ten meter band is rather flat across the entire band however the front to back ratio on 10 is very poor.
I suspect a bad 15 meter trap.

Can any one please tell me what the procedure is to check these traps. I have not figures out how to dip them. Is there a go no-go test to determine if a trap is bad? It seem to me they wopuld be rather easy to repair. I disassembled a 20 meter trap from the 40 meter add on kit that is not being used and not much to it. Would a bad 15 meter trap cause a bad front to back on 10 meters? I don't see why so maybe something else is wrong.

Pleas answer direct to me at: na0y@worldnet.att.net or na0y@arrl.net .

Thank you and 73 de Ken NA0Y

Jerry,
The only affect that using insulated wire, rather than bare wire,
will be that the antenna will be very slightly shorter than the
'normal' 468/f formula predicts. Unless you are doing precise 'lab'
quality testing, you'll probably never notice it.
Turning the ends of an antenna back rather than cutting it off,
works just fine. You do not have to 'short' the folded section of
wire for it to 'disappear' to the RF.
By the way you describe the section of RG-8x that your using, it
really does sound like 'junk'. Normally, RG-8x of reasonable quality
will work very well. Throw that section of coax away!

tnx fer different replies.
I believed the efficiency (performance) depended on actual area withing the square, triangle or circle, so an antenna designed for 40m should operate quite well on 30m provided it is properly matched. 50 ohm doesn't hurt, but not imortant as tuners are no problem to build, I already have two in the garden with a relay to switch.

Believe the antenna is almost omnidirectional - according to Y21BK antenna book which shows some diagrams. But the problem is that all information provided for hams are given with conclusions made that it should be 50-100 ohm feedpoint impedance, and information for different impedance is regarded as not optimum for a reason or other.

Also understand from ON4DX that the vertical radiation should be larger than horizontal for low radiation angle, but he didn't mention anything about operation of different bands.

My main interest is 30m, but I operate some cw constest which include 80 and 40m few times in the year, so if it is better than a W3DZZ trap antenna (actually LA1IC version) on 40m I it is interesting

Have remainder of a large loop which wasn't success and two inverted-L antennas (30 and 40m), will be pleased to remove all if I am convinced that a Delta Loop will replace them, some antennas go over the power line (cable), and it would be fb to reduce the crossing to a plastic rope
Also a problem having too many antennas from the 50' tower

If you have as much "juice" going up one side of the pair as is going down the other side of the pair, then it makes a poor ground. You've just moved the grounding problem back up to the top of the second wire. Right ? (I'm asking).

3519. ATR-10 Antenna Tuner question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-06 23:13:05 UTC
From: Craig Johnson <cbjohns@mn.mediaone.net>
Message-ID: <5YSP7.6386$183.718984@typhoon.mn.mediaone.net>
Source record: 153173

I am trying to help a friend with a new antenna system.

He has a balanced dipole, each leg 67' long, fed in the center with 450 ohm ladder line which comes all the way down to his Ameriton ATR-10 antenna tuner.

From past experience, a dipole of this type should be usable on all bands. However, when we try to tune it, we find that is is VERY touchy; ie. it appears to have a very high Q.

For background, the ATR-10 antenna tuner is a T-type tuner with a tapped inductor. There is 5-position band switch (??) on the front in which you select the inductor tap for the band you want to use. Single inductor position for each band range. Then you turn the two capacitors for SWR minimum.

I am able to tune it OK on 15 meters, right down to 1:1 SWR, but it takes a LOT of very careful tweaking. Same for 20 meters, and 30 meters, and 80 meters.

I didn't say 40 meters, because I can't get it below 3:1 on 40, no matter what I try. I know, 40 meters is EXACTLY the wrong frequency for an 80 meter resonant dipole, so it has to really work.

By the way, I tried my TenTec 277 tuner on this antenna system, and I could tune it on all bands. This tuner has essentially the same configuration but has more inductor tap positions (about 45). However, it is not nearly as touchy to tune. Maybe this means the TenTec is not as efficient (lower Q) ?

I am going to have him try lengthening his ladder line (by a few feet) when he goes on 40 meters, to see if this may put it in a different position on the Smith Chart and allow the tuner to match it. Haven't tried this yet.

Any comments about the "touchy tuner"? Is this typical for an efficient tuner in an "multi-band" antenna system?

Not uncommon. Years ago a friend asked me to fix his Microwave Modules 432-28 transverter. To make a long story shorter, the problem was a birth defect in that there was a parasitic path for leakage current that wound up going through the PIN diode T/R switch and lowering sensitivity. The circuit board was mounted inside a diecast box and was nearly impossible to remove without damage.

I figured out a way to fix it without even removing the cover. A resistor and diode on an external connector did it. I wrote up a paper and submitted it to Ham Radio Magazine. They accepted it and I waited for payment. And waited and waited..... It turn out they (so they said) sent the paper to Spectrum Internation, who was the importer and---you guessed it---an advertiser in hr, for "Editorial Review." It was never published, although I badgered them long enough that they finally sent me a hundred bucks for my trouble.

I have sent money to eham as I have posted a few 'for sale' items there. If what is being said about them is true, then it is the last contribution I make.

Source record: 153177

Foil-backed shingles, house wiring, pipes and metal vents, etc. all
will have a negative effect. Wood alone shouldn't be to bad at HF.
Most of my antennas are living in a forest.

Pete

I would like to get on 160 but am somewhat space limited although not as bad as many I am sure.

The Alpha-Delta DX-B would fit within my limitations BUT being unemployed and otherwise broke, even its reasonable cost is too much right now.

Can anyone supply a schematic of something similar that I could try to build?

I can string about 100 feet or so. I have tried an end fed / unknown length long piece of wire with no success.

Any suggestions appreciated.

Loose translation (enough to build the loop)

Magnet-Loop 80/40m (HB9ABX 20.8.2000)
==========
A MAGLOOP FOR 3.5 TO 10 Mhz BUILT AS FOLLOWS:
LOOP DIAMETER = 85 cm, 3 TURNS RG 213 OR
COPPER TUBE 10 TO 20 mm DIAM
TURNS SPACING = 2.5 TO 3.5 cm
COUPLING LOOP = 54 cm LONG, ONE TURN 1.5mm COPPER WIRE
CAPACITOR = 12 TO 125 pF, 4000 V
FEED CABLE = 50 Ohm Coax (RG 58) TO COUPLING LOOP

Its simply a 3 turn magloop. You would do well to try
and do a 6 foot or so loop -- a single turn is much better.
This will work though -- so have fun.

No comments on those Bert..but have you checked out the W9INN line of wire antennas? I host the W9INN Antennas web page on my web site which is listed below....

One of the most popular W9INN models is the MPD-5C which is a 5-band (10,15,20,40,80m) fan dipole with resonance on each band. It is also rated for 1500w pep. I have 299 DXCC countries on mine so far!

It employs what W9INN calls "resonactors" which act as a type of trap ...however there is no physical capacitor component in the antenna..therefore the 1500w rating is easily achieved and as such these "resonactors" are extremely reliable...

Source record: 153185

Tuners make lousy mobile antennas. Tuners don't tune antennas. They simply match impediances. Don't waste your money.

Ham sticks are dummy loads and are horribly inefficient. They're cheap and you get what you pay for.

Hustler would be the better choice. The coil is up high and they have prett good efficiency.

The best choice would be a high quality screwdriver. I use the High Sierra and love it. Go with a high quality screwdriver antenna when you can afford.

If you have 100 feet, you are almost there, especially for local stuff. You can base load it with a coil, wrap turns on a piece of pvc, until it matches. The key to 160 meters is the groundplane, stretch out as many wires as you can in as many directions as you can, even if you gotta run them along the sidewalk in that crack where the edger goes.
you should be able to work half way across the country when conditions are good.
Also, the higher you can get your 100 foot were up, the better, even if it has to be in the shape ov an inverted l or v.

Dennis,
With HF mobile antennas, in general,the uglier they are,
the better they work. With any loaded antenna the larger the
loading coil, (within reason), the more efficient they are.
I've seen both Hustler and Hamsticks work very well on
20 and 10 meters. One 'trick' with the Hamsticks is to use a
mast extension to get part of the Hamstick above the roof
line of the vehicle. It seems to help. The same basic idea
witht he Hustler, get the loading coil above the roof line.
Good luck...

Craig,
I wouldn't say it's typical for multiband antennas, but
it is typical for some tuners. All tuners are not created
equal, they have varying 'tuning ranges'. The tuners that
seem to handle about anything usually have larger components
than others. I think if you 'popped the top' on your friend's
tuner and your's, you might see the differences.
Changing the feedline length can make a big difference, I
would definitely give that a shot.

Message-ID: <_IWP7.49220$Sx.13266019@news1.elcjn1.sdca.home.com>
Source record: 153189

I should know better. Anyway I like the jazz on the station low in the FM broadcast band, although it is very hard to receive at my place, so I decided to put up an external FM antenna from Radio Shack that was lying around the place - it looks like 2 folded dipoles in an X configuration with a bit of slotted ribbon between the feedpoints.

I ran some leftover 75 ohm TV coax to the radio in the garage and, with a bit of turning around of the antenna (mounted horizontally), I got a decent signal, with just a tiny bit of scratchiness, but certainly listenable.

Encouraged by this success, I cut another piece of coax (same stuff) and ran it to the radio in the living room from the same antenna. The coax run is a bit further, and I decided to leave about 20ft of coax coiled behind the radio in the living room, since I am planning to move it someday to the other side of the room.

The reception in the garage is great, but the radio in the living room is patchy, and reception can only be improved (although not to the extent of the quality I got in the garage) when I jiggle around the 20 feet or so of leftover cable. It seems to improve a little bit when the cable is run vertically away from the terminals on the back of the radio - I guess the terminals on the back of the radio are 300ohm, but I think it just says "FM ant". The ones in the garage are definitely low impedence.

Before I go ahead and make things worse, would be interested to know whether:

a) cutting the coax shorter would help

b) using a balun at the back of the radio would help

c) I should have used 300 ohm ribbon instead of coax

d) maybe the antenna should be polarized vertically
etc...

Thanks in advance.

W.

First, put a 75 to 300 ohm balun at the antenna. Those crossed folded
dipoles are 300 ohm. Next, it sounds like the last chunk of cable is acting
as the antenna for the inside radios if moving it makes a difference. How
did you make the connection at the first radio?

Mr. Wombat asked about his FM Broadcast Antenna:

A simple solution might be one of those inline preamplifiers of the sort that has a remote amplifier that mounts close to the antenna and a power injector down near the receiver. Typically 10 dB gain. These sorts of gadgets are Cdn$30 which should be US$20 (but might be US$25 just cause). Stock No. 15-1117 (a.k.a. 1501117). If it doesn't work out, they'll give you a refund if you can bring it back in decent shape.

J Harvey wrote:
"If you have as much "juice" guing up one side of the pair as is going down the other side of the pair, then it makes a good ground."

A ground wire of low impedance develops a low voltage drop. Ohm`s law applies for r-f, that is, the magnitude of the voltage drop is IxZ.

The artificial ground is usually a series-resonant circuit which includes the reactance of the ground wire. All that is left to impede current at series-resonance is resistance in the circuit. This is of two kinds. There is the old-fashioned heat producing resistance of the wire itself. Then there is the radiation resistance which accounts for the r-f that escapes the wire without conversion to heat, light, or any form of energy. It is a fraction of the r-f applied to the wire which escapes without conversion into any other form of energy. This is the way that a wire which is intended to be an antenna works.

I proposed using a transmission line as a relatively low-impedance path to ground because a resonant length could be used to eliminate reactance. A low impedance produces a low voltage drop.

A single wire can be resonated for a low voltage drop also, but it carries all the antenna current and has no equal but opposite image alongside to prevent radiation as does parallel-wire transmission line. The single wire is prone to radiate a lot.

From the discussions in this thread, many perceive the current in a parallel-wire transmission line as "going up one side and down the other". That doesn`t fit observations very well.

Across the output terminals of a transmitter appears an r-f voltage which has a continuum of alternating values. The value at any instant emerges from the terminals and travels as a potential directly across the wires as it travels from the origin and away from the transmitter on both wires maintaining the potential difference between the wires as best it can as it travels along at nearly the speed of light.

The marbles packed into a tube analogy does not work well for an r-f transmission line.

The transmission line can be considered as having a neutral plane equidistant between the wires. The instantaneous charges on the two wires at a certain distance from the transmitter are equal but of opposite polarities with respect to the neutral plane. The current-produced magnetic lines of force around the two wires are equal and opposite at this point along the transmission line too. Thus, if you are outside the immediate vicinity of the wires, the fields, electric

and magnetic, add to zero. The line can`t radiate.

A properly balanced parallel-wire line won`t radiate when used to carry the differential signal applied to it. With the right stuff employed this can be r-f destined for the earth as well as r-f destined for the radiating element. There are situations where this is desirable.

R-F will be picked up by various stray methods. One path to ground for this stray energy is by the common-mode path of the parallel-wire transmission line. This essentially uses both wires of the line in parallel. Almost zero volts are produced by this method between the two wires. The impedance to stray currents in this mode is mostly the radiation resistance of a 1/2-wave of wire, which in this case happens to be parallel wires in a transmission line (almost the same radiation resistance as a single wire).

The subject is not exhausted, but right now I am becoming exhausted.

Best regards, Richard Harrison, KB5WZI

W -

Your radio receiver probably accepts a 300 ohm antenna connection.
The "X" configuration FM dipole is a standard "omni directional" antenna.

You can check (Radio Shack sheet with antenna), but this antenna should
have a 300 ohm impedance. You can feed it with standard twin lead.

If you do use 75 ohm coax cable (RG-95 or RG-6 used by cable and satellite
TV systems),
you will need an outdoor matching transformer at the antenna (300-75) and
another one at the FM receiver (75-300).

You can get better reception of your favorite FM stations with a channel 6
or FM band yagi antenna.
TV channel 6 is right below the 88 MHz edge of the FM radio band. I picked
up a very long (12 feet) FM band yagi that was being thrown out several
years ago. Very impressive reception (90 miles from large cities - in any
direction !).

Most FM radio stations broadcast both vertical and horizontal polarization.
There are exceptions to this.
For example, the Knox College radio station in Galesburg. IL only broadcasts
with a horizontal polarization (no vertical component).

What would make signal stronger (better)?
Keep cable runs practical and short (no large loops of cable)
If you use coax, properly match to the antenna and receiver with matching
transformers (baluns)
Horizontal polarization should be fine
You can use 300 ohm twin lead, if you have that available. Does not
require matching for your set-up
A directional antenna pointed in the desired direction of the FM station.

GB

Not really. It may act as a bulk of wire, but it's not near as precise
as doing it with uninsulated. I've never seen any signs of arcing
though the insulation and I've run some heavy power levels with high
voltages at the ends. If you turn back a lot of insulated wire, you
won't see the effect of that amount as it wants to play like a narrow
coil of sorts. MK

Mark,
LOL!

Aside from the humor, I have only one beam that uses a gamma match and
I do not use a balun or an unun. Performance is fine, no RF in the
shack, stable SWR; so if it ain't broke..........

73,
Howard

> > the pair, then it makes a good (sic) ground."

I wrote "poor", not "good". Sort of changes the meaning a bit. :-)

"Richard Harrison" wrote a great deal:
<snip>
> ...but right now I am becoming exhausted.

Using a WebTV user interface would make anyone tired. I'm tired just
thinking about it... [:-) !!!]

...ANYWAY...

CAM was apparently suggesting (?) using two ground wires (a transmission
line) with currents of opposite phase (in the normal twinlead fashion ?) to
cancel the radiation from the ground current.

Obviously, this is one of those "It's turtles all the way down" (Carl Sagan)
sorts of situations in that the current on the second wire, which is
cancelling out the radiation from the current in the first wire, has brought
the need for an artificial ground right back up about 1cm from where it
started.

"Richard Clark" understood the point and replied:
> So it would seem.

We certainly could use a Portable (Fractal?) Ground around here.

I wonder if a 200 litre steel drum filled with old anvils and other bits of
scrap metal would present a sufficiently large self capacitance to make a
difference at 80M and up ?

Does that manual cover Astros? If so, see exactly where the module is (or actually should be) in our '01 Astro.

I posted a while back regarding the mysterious absence (according to our dealer) of a receiver module in our Astro despite the fact that keyless entry is listed on the build code sticker on the door (and when looked up via GM's VIN cross-reference computer). Dealer made up for it by having an aftermarket unit installed. Would rather have the factory unit if its not in there, or have it working correctly if it is.

Thanks

What if one put an inductance in one leg of the ground and a capacitance
in the other leg thus shifting the relative currents 180 degrees out of
phase?

Nope, it's not the dipole's fault - it is the feedline length's fault.
If you make the feedline 3/4WL on 40m, it will work very well.

> I am going to have him try lengthening his ladder line (by a few feet) when he goes

Check out the feedline lengths on my web page. My tunerless dipole is
only four feet shorter than his dipole. A good overall feedline length
would be 100ft.

Message-ID: <3C107B43.66764B0D@eznec.com>
Source record: 153210

It wouldn't be practical because of the extremely close spacing required. If you used #12 wires they'd have to be spaced just 0.007 inches apart to make a 50 ohm line.

(Anybody with EZNEC v. 3.0, including the demo version, can quickly make this calculation. It might be the very quickest way, but it's easy if you already have EZNEC. Open any description file. Click "Trans Lines" in the Control Center. In the Transmission Lines Window, right click in a white cell in either the Z0 or VF column. This brings up a dialog box. Choose "Two parallel conductors" on the left. Enter the wire diameter in the Wire Diameter box (you can enter it as an AWG wire gauge, like '#12', if desired), and center-to-center spacing in the Wire Spacing box. You'll see the Z0 in the frame at the lower left. Want to know the diameter of the AWG wire? Enter zero in the Wire Spacing box and hit <Enter>. The error message will tell you the minimum allowed center-to-center spacing, which is the wire diameter. This calculation uses the full hyperbolic trig function formula, not the common logarithmic approximation. Click Cancel when done.)

> Jan-Martin
> LA8AK

The inverted L would need a good ground screen to work well. And even then it would mainly be best for long haul stuff. I wouldn't want to use an inv L as an everyday antenna on 40m. The loop should do a good bit better on medium distances. Myself, I would prefer a dipole. For a 40/30 antenna with a single element, I'd probably use a 40m dipole fed with ladder line and a tuner. It would also work great on 30m. But I noticed you also want 80 meters also. In that case, I would use an 80m dipole fed with ladder line and a tuner. It would act as two half waves in phase on 40m, and as an appx extended double zepp on 30m. The main reason I prefer dipoles is most of the current is usually higher in the air for the most part. If you have a loop with sections fairly low to the ground, you have higher ground losses for one thing. Also more prone to blockage by nearby objects. I like as much of the antenna to be well up in the air. But other than that, the loops are ok. MK

> Jim
> KG4NEL

I'm sure it has a slight effect, but I don't think wood in itself is
too bad. Like another said, wiring and pipes will usually be a worse
problem. If the roof had a metal layer that would be real bad news.
I've got a 40m dipole in my attic that is strung through the 1x4's
under the roof decking."all wood" I haven't noticed any real problems.
I kept as far away from ac ducts, wiring, etc as I could. Wood is not
rf invisible, but pretty close to it at lower frequencies. I'd rather
be outside though...My attic antenna is my "storm" antenna when I'm
too scared to use the taller ones outside. Some days I'll stay
grounded out all day if lightning is anywhere in the area. Sometimes
you'll get a lone pop out of the blue when it's like that. Had one
nearby about a month ago. But I was grounded out due to being
paranoid. It's those lone pops that will usually eat your lunch. I
like to play it safe being it would wipe out a few rigs, my puter and
who knows what else. Ones still in warranty...I'd get sick if it got
popped.. waaaahhhhh :(Icom is not cheap on fixing lightning fried
rigs and the warranty wouldn't cover a cent if it was obviously fried.

Hi everyone:

I have done a Slim Jim of aluminium tube and i can't get a swr lower than 1.5. Moving up and down the feeder point it goes up. I always heard that this antenna had a excelent performance. 1.5 swr i consider a discrete performance more if you compare with a J or a GP.

Did anybody made one?
What were your practical experience?

Thanks

Pedro,

hey in most books they will tell you anything below a 2 SWR is fine but in
VHF and above you would LIKE as low of an SWR as possible
what i would do is stick a dummy load at the antenna end of the coax and
check the SWR chases are it will not be flat as it should be and if it isnt
that is why you cant get the SWR any lower
good luck

True.

>But where? Power is the only thing that will heat the wire, so if we say it
>is at a voltage maximum, then the power loss will be E^2/R.

Nope.

>Now E is going to be
>large, and R is going to be concomitantly small, so this seems to be the
>right place for heating to occur.

Nope. Wrong. Try again.

> Similarly at a current maximum, I^2*R is the
>equation, and although I^2 is large, R is at least decently large enough to
>heat up the works..

In the antenna described, I^2R heating will be the one to check. But it will be
very small if the antenna is made of typical copper antenna wire.
>
>So how about it, gurus. Sit back in your hot tubs, pour another glass of
>champagne, and ponder upon the question.

>
The points of greatest heating will be at the current loops. The first current loop will be 1/4 wave from the far end, and there will be current loops every 1/2 wavelength from there - 3/4, 5/4, 7/4 wavelength from the far end.

But the heating effect will be very slight - probably not enough to melt the snow.

Don't know what a Slim Jim is but a 1/4WL vertical with flat
radials often has a feedpoint impedance around 35 ohms. An
SWR of 1.5:1 is perfectly OK and doesn't even require a
tuner.

J. Harvey wrote:
"Richard Harrison" slightly misquoted J. Harvey:
---I wrote "poor", not "good".

I am sorry. It was not intentional.

J. Harvey actually wrote:
"If you have as much "juice" going up one side of the pair as is going down the other side of the pair, then it makes a poor ground. You`ve just moved he grounding problem back to the top of the second wire. Right? (I`m asking)".

J. Harvey is right. "You have as much "juice" going up one side of the pair as is going down the other side of the pair" in a balanced transmission line.

A wave traveling on a transmission line isn`t launched only on one wire to race around the line circuit to complete a round-trip to the starting point. The wave is launched on both wires at once. Whichever wire happens to be "plus" at the instant will be accompanied by its "minus" equivalent just across the short distance on the other wire. This place in the voltage cycle, a particular magnitude, travels down the transmission line at the velocity of propagation allowed by the line, or nearly at the speed of light on most lines. The "juice" goes up or down a transmission line on both wires of a pair together.

The idea of a 1/2-wave grounding conductor is to eliminate reactance. The 1/2-wavelength is resonant, has no reactance, repeats impedance between ends, and adds only resistance to the ground path.

The idea of using a parallel-wire transmission line instead of the usual single-wire ground lead was to avoid radiation. Balanced transmission lines don`t radiate. To maintain balance in the transmission line between the radio and the earth, it may be better to use center-tapped balun coils at each end of the transmission line to complete the radio to earth connection. That assures both wires in the balanced transmission line equally share the radio ground current from whatever stray source.

Differential current in the transmission line is from the power destined for the antenna. We often want it radiated by the antenna and not by the ground wire.

Stray current is carried by the common-mode, as proposed. Voltages from the common-mode have the same polarity and magnitude on both wires at any distance along the line. Because we didn`t provide any clever balancing mechanism for the common-mode current, it will produce

radiation and the impedance to earth will be the radiation resistance of a 1/2-wave wire, as Reg pointed out. The good news is that most of the antenna current is carried in the differential-mode which does not radiate from the transmission line.

Best regards, Richard Harrison, KB5WZI

As a matter of fact, I have used the Palomar FS-1 on hamsticks. On 10m,
they are very close to a screwdriver. If I remember right, on 20m my
hamstick was 2dB down from my screwdriver (without a top hat). 2dB is
hardly discernible on an S-meter. A quarterwave rod will get you into
trouble running 20m mobile. Note I said the mobile hamstick performance
was "acceptable" on 10m-20m. And hamstick performance probably varies
from manufacturer to manufacturer.

CAM, W5DXP wrote:
"What if one put an inductance in one leg of the ground and a
capacitance in the other leg thus shifting the relative currents 180
degrees out of phase?"

Maybe we need more information. Terman says:
"For the reflection coefficient to have a phase angle of exactly 0 or
180 degrees, it is necessary that the load impedance have the same phase
angle as the characteristic impedance. In the case of radio-frequency
transmission lines, this means a load that for all practical purposes is
resistive. (page 93, 1955 "Electronic and Radio Engineering")
We do have a real load (the antenna) on our transmission line.

50 ohm transmission line transformers are wound with magnet wire spaced
as closely as possible. 50 ohm balanced transmission line doesn't buy you
much. It has just as high an SWR as coax and is close to being just as
lossy. It usually arcs at a lower voltage than good coax. The beauty of
450 ohm or 600 ohm transmission line is that it reduces the matched line
current by a magnitude or more thus reducing I^2*R losses.

If the current going down one wire is cancelled by the current coming up the other wire then the resulting current is zero. The top end is then disconnected from ground. It is an open circuit. The ground wires might just as well not be there. Absolutely useless as a ground connection for the same reason that it won't radiate. Any CB-er knows that.

Message-ID: <aj6Q7.6657$183.807238@typhoon.mn.mediaone.net>
Source record: 153034

Thanks, Doc.

Yes, I know all tuners are different, and this is my first experience
with the ATR-10. By the way, we did open it up, and it looks
BEAUTIFUL inside. It has huge components, and huge wires
connecting the parts. The balun is a torroid arrangement, and it is
about 3" in diameter. There are two inductor coils, the larger
being about 8" long and about 2" in diameter. The smaller one switches
in when more inductance is needed. It is about 3" long with smaller
diameter (maybe 1") with wider spaced turns and larger gauge wire.
The two capacitors are also large (about 4" cross section) but the
spacing is not terribly wide. Maybe 1/16" between plates when meshed.
Not really good for high power but should be fine for his 100 watts.

(My TenTec is tiny in comparison. The main coil there in it is jsut a torroid,
and the inductor switch on the front panel points to the various turns of
wire on the torroid. Certainly not a good idea for high power, but works
fine for 100w.)

We bought this ATR-10 tuner used without contact with the original owner.
Could it be a balun problem? The balun is configurable as a 1:1 current
balun or a 4:1 voltage balun. The instructions say to try the 1:1 first, and
if it doesn't work properly to try the 4:1. It is currently in the 4:1 voltage
configuration.

Hi Cecil.

Good to hear from you again.

Yes, I am very aware of your tunerless dipole. I have used this idea and modeled my own dipole extensively (with EZNEC). I can see how my dipole can go on all bands with no tuner, but by changing the length of the ladder line.

We don't have a measurement for my friend's ladder line length. We would have to take it down to do this accurately enough to put into EZNEC. We will try experimenting by adding to the length to see if we can find a sweet spot for 40 meters.

You're comparing the Ham-Stick antennas to the wrong stuff. Of course
it's worse than a regular quarter wave antenna with radials! But
that's not a mobile antenna unless you have a really interesting
vehicle.

You should compare it to the alternatives a person might have: such as
a Bugcatcher, the Hustler line of mobile antennas, a whip with an ATU
at the base, etc...

Artificial Ground Thread Folks:

I got worried last night, I began to think that Richard was on to something here...
and so I did some checking.

[snip]
> J. Harvey actually wrote:
> "If you have as much "juice" going up one side of the pair as is going
> down the other side of the pair, then it makes a poor ground. You`ve

> nearly at the speed of light on most lines. The "juice" goes up or down
> a transmission line on both wires of a pair together.
>[snip]

Uhh... methinks... Richard is mixing his metaphors... particles and waves.

Actually electrons [and any other charge carriers free to move] move along the transmission
line and generally "drift" along quite nicely in a well defined direction between points of
differing potential along the direction of maximum potential gradients.

Waves on the other hand, may be "launched" into a media as he states. However, in the
case of TEM mode transmission, which is of the most direct interest to us "old fashioned"
HF hams, the particle and wave modalities are emminently reconcilable.

Thus "what goes up must come down" the ground wire, be it parallel or single wire construction.

The problem with Richard's new parallel wire transmission line ground lead "invention" or "discovery"
is the problem of "dressing" the ends of the leads near the actual ground connections. There will be
two of them and they are quite far apart. He's gonna have a tough time with that.

For... the ground of which he is so fond is actually of infinite extent and although he can connect to one
part of it nearby to his transmitter located only 1/2 wave away... the other ends only out there somewhere
near "The Restaurant at the End of the Universe". [Post humous appologies to Doug Adams...]

Thus, one wire would have to be attached to the ground nearby [1/2 wave away I believe was the premise.]
and the other wire would have to be "dressed" so as to connect to that big #00 lug behind the Restaurant at
the End of the Universe to pick up the returning charges.

I was interested in what the CCITT's Ground Engineers had done aobut this.

Here in Cary, NC I'm a long way from where the CCITT's International Ground comes ashore there at Dinner Key
in South Miami to check the American connections, and so last night, during my regular 15m CW sked with him,
I asked Dr. Nehoc Nahtan, RI1N, of the Indonesian Institute of Technology to check the actual connections where the
CCITT's IG comes ashore in Malaysia.

RI1N's research lab is near the beach where the IG comes ashore there in Malaysia.

Well this morning around daybreak, when the grey line was lined up between us, I re-skeded with him on 7.013 Mcps
CW and he told me that indeed the CCITT had brought two parallel leads ashore for the connection and he told me
that the two leads were not parallel for very far! I suspected as much.

In fact, he confirmed that the CCITT Ground Engineering Team had dressed the two leads of International Ground in
two different directions. The IG leads headed off in different directions from the Malaysian beach near his lab.

One was dressed off towards the South aimed at the CCITT's IG star-point just South of Austrailia and the other...
was headed towards the InterGalactic ground star-point just behind the Restaurant at the End of the Universe.

Dr. Nehoc used his new Meade computer controlled desktop telescope to confirm that side of the connection.

I later confirmed all of this by "Communicator" with Dr. Spock, ST1AR who is the InterGalactic representative from

Vulcan to the InterGalactic Ground Consortium. I have a regular sked with Spock on the StarTrek Communicator
Channel 16.

Has anyone noticed a distinctly higher level of QRN on the "Communicator" channels lately?

Anyway it's Dr. Nehoc's thought that the USPO will never grant Richard Harrison a patent on his balanced 1/2 wave
ground wire concept, because it simply cannot be dressed correctly at the appropriate connection points and so a
demonstratable model simply cannot be constructed in order to convince the examiners.

It's just another "perpetual motion machine" said Spock!

And so I guess that Thomas Edison's patent record is safe from Richard.

That makes no sense whatsoever.

Fences are out in the sun all day, every day. I have plastic
fence insulators that have been in place for 20 years without any
sign of deterioration, and some I put up in the past three years
also doing fine.

I don't know what fence insulators you found, but they are not
representative of the normal products in that industry.

Unless maybe it wasn't the sunshine... Most of the plastic standoff
type insulators are NOT physically strong. They are not intended to
hold the wire tightly but merely position it out from the fence (the
wire slides thru a channel). Perhaps you merely broke the insulator
and the sun had nothing to do with it?

Anyway, the standoff type was NOT the suggestion. The egg-shaped
ones were the topic of discussion. They are physically strong.

For 10 or 20 meters...the Hustlers are better (more efficient) than the hamsticks. And on those bands, wind loading shouldn't be an issue.

On lower bands (80, 40...) wind loading is an issue because the loading coils are larger.

Mainly the dielectric, but the higher impedance also helps. Air dielectric 75 ohm line would require 0.016" outside-to-outside spacing without the dielectric, which still wouldn't be practical. (I believe the person asking the original question specified air insulated line.) 72 or 75 ohms is just about the practical minimum for parallel conductor lines, with dielectric. Coax can be made with a considerably lower impedance because of the fact that the fields from the conductors completely couple to each other.

Cecil makes an important point. A lot of people mistakenly think that the low loss of air insulated parallel conductor line is because of the lack of dielectric. It's not, directly at least. The low loss is due simply to its higher impedance, which lowers the current and therefore the I^2*R loss, as Cecil points out. The air dielectrtric helps only in that it gives you a higher impedance for a given wire size and spacing. Likewise, foam or mostly-air insulated coax has lower loss not because of lower dielectric loss. The loss is lower because the lower dielectric constant allows a larger diameter center conductor for a given Z0 and outside diameter. The RF resistance of the larger conductor is lower, so again the I^2*R is less.

It's not that non-air dielectrics don't have loss and that foam isn't less lossy than solid plastic -- it's just that this loss is very much less than the I^2*R loss at any frequency in the UHF range and below, so it doesn't contribute a noticeable amount to the total. But dielectric loss increases faster with frequency (it's proportional to frequency) than I^2*R loss (increases as the square root of frequency), so at a high enough frequency, the dielectric loss catches up with the I^2*R loss. In coax, this happens in the vicinity of 1 - 10 GHz, so above that range, the lower dielectric loss of foam is helpful. The same effect undoubtedly occurs with twinlead, probably at a lower frequency, but also probably well above the frequencies where it's commonly used.

Roy Lewallen, W7EL

Reg, G4FGQ wrote:
"It is an open circuit. The ground wires might just as well not be there."

That is true for a 1/4-wavelength conductor in the ground path. Transmission lines have been directlly supported by 1/4-wave metal supports firmly connected on their ends opposite the line to the ground plane. These have been called metal insulators.

This is not the case for a 1/2-wavelength connection to earth. A 1/2-wavelength conductor has only loss and radiation resistances separating its ends. It is a series-resonant circuit.

Best regards, Richard Harrison, KB5WZI

I don't know about the Radio Shack stores in Texas, but the Radio Shack.Com in my area sells Amphonol pl-259 silver connectors. They might cost a buck or so more, but they do appreciate me visiting their store.

Even the local Ham Radio Outlet on the other side of Phoenix from me is happy to help me when I walk into their store. Even visiting the HRO store in San Diego, the manager there was great to talk with, even though I couldn't find a thing I needed that day.

But if the people at TT like having the personality of a door knob..... so be it.

A 1.5:1 SWR is perfectly fine. Concentrate on keeping your feedline losses as low as possible, this will benefit you much more than a few points of SWR one way or another.

Wouldn't make much difference in the result--it's been done at the
California shootouts. The ham-
sticks are the WORST possible choice on most ALL bands. Period. I have a
friend that thinks the
hamsticks are the cat's "meow". Of course, he has never compared them to
anything else, so he can't know what he's missing. Myself, I go for the
best signal I can get being that a mobile is a
compromise even in the best case. It's why I use and, also, build the
Carolina Cyclones! LOL!

Hamsticks have worked great for me on 20 and above. I have worked all over the world, busted pileups, and enjoyed the heck out of my mobile operation. They're cheap enough so if you lose one, it ain't no big deal. I've heard good things about the Hustler system although they look a bit weird and bulky. I concur that the tuner type systems don't make any sense in a mobile operation because all the radiating takes place in the tuner (in your trunk) not the antenna.

As for all those who deride anything but a full-size screwdriver: It would be a mistake to get so worried about finding the "best," you get paralysis by analysis. You'll end up deciding you can't work mobile because it is a screwdriver or nothing. Hamsticks are no darn good, Hustlers have too much wind load or you can't afford (or don't want the hassle) of a screwdriver. Just get on the air and enjoy!

==========

Roy, only if they were air-spaced.

When embedded in plastic, polyethylene or PVC, as they MUST be to find some physical support, a practical 50-ohm twin-line has wires spaced considerably further apart.than you say.

In practice, 75-ohm plastic insulated twin is quite feasible and is still available (or it was). It matches very nicely to a centre fed 1/2-wave dipole and was very often used in that application.

The dimensions of low Zo twin-lines can be estimated by using some of my RJELINE programs. Eznec, primarily intended for very different purposes, is too long-winded.

Regards, Reg.

From the latest "Mysterious Antennas Monthly":
>
>
Greetings from Tokyo and all the members of TIARA (Tokyo International
Amateur Radio Association). I know I promised you a series of articles
on Japanese amateur radio, but there is something so exciting I just
have to take a break and tell you about it.
>
>
It all started with the work that Ed Coan (AH7L/7J1AAE) did on antenna
pattern plotting using his personal computer and the A-to-D converter
in his FT-1000. The circular, and even backward antenna patterns of
some of our local TIARA club members brought home the point that what
a good station needs is a good antenna. Ed's antenna looks great and
the results verify it. He works regular schedules into Colorado and
Maine,just like sunspots don't mean anything. My mini-beam just could
notcompare.
>
>
Well, I got to thinking about what we Tokyo apartment dwellers could
do and realized that space is THE problem. How do you fit a full-sized
beam on a balcony? Loading coils are the answer and the problem at
the same time -- the antenna radiation resistance drops as reactance
is substituted for length. High current loops develop and the power is
dissipated in the antenna instead of being radiated. If only the
antenna didn't dissipate the power. Hmmm....let's see, P=E2 /R; now if
R were 0 then...
>
>
From my work, I have some contacts in research groups over at Tokyo
University. Better yet, I knew a Japanese ham that is a graduate
student there. The thought running through my head was to build a
super-conducting antenna. This requires cryogenics, i.e. temperatures
around minus 279 degrees Centigrade. I was able get the university
folks interested in the project and we built a 10-meter dipole test
silicon wafer. They put together a lot of serial coils by "re-work" on

the wafer; they were able to connect them so we had a super-conducting yagi.
I took my TS-930 transceiver down to the lab for the first tests, but before we could test it, actual measurements showed it was resonant on 3.126 MHz. It seems that the normal equations for inductance don't work with super-conducting materials — you need a lot fewer turns to get the same results compared to room temperature. Many measurements and trials later, we had a ten-meter resonant wafer. This time we put a 40-element beam on each wafer and stacked 4 wafers in the same assembly. That made a 160-element array on 10-meters in less than a half-foot cube (15 cm3).
>
>
The first test didn't go too well. I connected my TS-930 to the super-conducting wafer antenna and tuned it for 10 meters. At room temperature, we couldn't hear anything. Using a heat pump, the lab technicians started lowering the antenna's temperature toward the super-conducting region. I was really impressed by how small the equipment is, and started thinking it might all fit in the shack. Just then, the TS-930 froze solid, which had a negative effect on its operating characteristics. This wouldn't be so easy after all; the coax
connection would need some study!
>
>
We reworked the wafers to put inductive coupling on them, but I could find no way to efficiently couple to it from the conducting array. Fortunately the lab technicians came up with a new ceramic material that
passed RF but not heat. Probably, something that Kyocera invented just for this use. I sent the TS-930 to the ham shop in Akihabara and asked them to touch it up for me. My friend Suzuki-San, JH1WWC (store manager
at the ham shop), asked exactly how the paint had been peeled off around
the coax connector -- lightning maybe? No, I assured him -- just low temperature exposure, without saying how low the temperatures were. The
project had to stay secret and besides, Suzuki-San can repair anything!
>
>
Since it looked like it might be a while before the TS-930 would be repaired, I brought out my TS-940. I had already placed an order for a Yaesu FT-1000 anyway. After verifying that in the super-conducting range the antenna was resonant on 10-meters, we connected the TS-940. The ceramic material worked and the rig operated well as we began the cooling cycle. The band seemed dead even with the antenna at -150 degrees C. It took another 10 minutes to get to the super-conducting range -- then the TS-940 blew up. It seems our antenna had a bit more

gain than the TS-940 front-end could take. Later measurements showed 500 volts coming out of the coax. A little hard to believe, but then what do
I know about cryogenic LSI antenna technology? The TS-940 was also returned to Suzuki-San, but this time he frowned a bit -- the front-end board did look like it had been hit by lightning. Not to worry, Suzuki-San can repair anything!
>
>
The FT-1000 arrived just in time to be able to continue experiments. We built a QSK attenuator to protect the receiver. With the LSI wafer antenna still inside the lab, we decided to try to make a contact on 10-meters. What a shock when we got it working! The first thing we heard was a couple of W2's talking locally on 10 meters and that was with 80 dB of attenuation. We had the antenna array on a rotatable mount; I moved it about a half-degree and the W2's disappeared. What beam width! We tuned them in again, and they were just about to sign off, so we thought we would try to work them. The rig was tuned up at 50 watts on a
dummy load; we switched in the wafer antenna and gave N2BA a call. The noise was unbelievable -- an ionized ray shot out from the antenna and hit the wall of the building. Before we knocked a hole in the band, we took a piece out of the lab wall! Ever wonder what an antenna pattern looks like in three dimensions? There was a oval hole in the wall of the lab -- about 1-cm high by 2-cm wide. We cut power quickly. N2BA came back on frequency a few minutes later and said he was using his back-up rig; something had taken his main rig off the air. For some reason, the station he was talking to never came back, so we decided not to transmit again until we knew for sure what was going on.
>
>
As near as we can tell, the antenna array has 620-dB gain over a dipole, but with a beamwidth of 0.75 degrees using the 60-dB points. With 50 watts output, the effective radiated power is 55 quadrillion watts at the center of the beam (5.5 with 13 zeroes). As soon as the University realized what we had built, the entire project was taken away from us and turned over to the Japanese Self-Defense Force. Amateur radio "tinkering" has contributed to something, but I am not exactly sure what. I haven't the slightest idea what was in those wafers or how to build another set. Do you think someone may be interested in this
idea for Star Wars/SDI?? What I'd give to use a much smaller set in the next CQ World Wide Contest!
>
>
A few months later, the University contacted all of us and asked just how close we had been to the antenna when operating. As best as I can figure, we were in the null behind the array. From what has been said so far, it looks like a secondary use for our antenna may be as a mass sterilizer, but confirmation will have to await the results of our

medical tests. If our antenna ever hits the market, it looks like
remote operation may be desirable.
>
>
As I am writing this, I have been informed that my friend Suzuki-San
can't fix everything after all. He's written off the TS-930 and
TS-940, and I just found out that before the university terminated the
project, they tried one more time with my FT-1000, but without the
100-dB attenuator to protect the receiver. Its front-end now matches
the 940's and it looks like it will be a while before I am on the air
again.
>
>

Oh, and yeah, a Vee Beam is the feed-end half of a Rhombic, half
Rhombic, half-assed Rhombic, it's in the ARRL Antenna Book.

3616. Hy-Gain 18HTB part

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-08 00:38:50 UTC
From: dothetime@hotmail.com
Message-ID: <141e2b2a.0112071638.61d5468b@posting.google.com>
Source record: 153068

I acquired a new old stock 18HTB Hy-Gain HyTower vertical. I am
missing one of the two insulators. It's a two inch inside diameter,
four inch long plastic tube.
Anyone got one laying around?
Anybody got any suggestions?
How about a piece of PVC plumbing?
I don't think Hy-Gain is offering parts.
Thanks for any help.
Dave K2DHK dothetime@hotmail.com

I've seen people advertising a single magnetic loop having "front
to back gain". Or vertical antennas "all band from HF to 70 cm"
and in small print "with the aid of a tuner".
There are a lot of funny things on ham magazines :)
Ciao.

I have been testing a 33ft by 33ft Inverted-L for portable use (80-10m) and stumbled upon it being an effective restricted space antenna on 160m. I have had SSB QRP between Seattle and San Francisco and CW with Japan (50w). I use a 12 --16ft radials. It is fed with 300 ohm balanced line. You get both a low angle and a high angle lobe pattern. Not as good as a 66 by 66 but still very effective

Coax is unbalanced. The MLB is not a balun. The only reason the manufacturer calls it that is because the term balun has been misused and misunderstood by SWLs for so long. It is a 9:1 transformer. Yes, I have one (home made. I' not paying $65.00 for something I can build for $5.00). Yes, they work.

Your wife and mine need to compare notes!! But seriously Dennis, as far as ten meters goes, I use a Wilson 2000 Trucker antenna on the trunk of my 99 Intrepid and get absolutely unbelievable reports. I worked TF8GX the other day and he told me I was stronger than all the US stations he had worked. Of course I'm sure my tiny little 200W amp helps a bit! Good luck on your choice, it will be worth it when you finsh the installation. I am having a blast on 10m mobile.

==============================
Inductance in parallel with capacitance, each wire of same reactance
to give equal currents, results in a very high impedance. So top end
of line is isolated from ground. Might just as well not be there. All
CB-ers know that.
```

==========
An excellent suggestion. But why not fill drums with atomic waste from de-commissioned power generating stations. Uranium is extremely heavy stuff. This would result in an even greater capacitance. In addition, the residual radio activity would make ground conductivity in the vicinity much greater. From DC upwards. Waste not - want not !

The ARRL should now go fully commercial and corner the market in 200-litre steel drums. Show a little more enterprise.

I have been seeing on a TV infomercial where they are hawking a so-called range booster which is some kind of a printed circuit sticker that you paste on the back of your phone and then reinstall your battery over on top of it. They say it is supposed to increase the power/range of your cell phone.
Do any of you have an opinion about this device? Personally I think it is a scam and a bunch of BS. I have never gotten any true quality merchandise from an infomercial. Thanks for your opinions.

No external antenna...

The keyless entry system uses rolling code technology. Rolling code technology prevents anyone from recording the message sent from the transmitter and using the message in order to gain entry to the vehicle. The term "rolling code" refers to the way that the keyless entry system sends and receives the signals. The transmitter sends the signal in a different order each time. The transmitter and the RCDLR are synchronized to the appropriate order. If a programmed transmitter sends a signal that is not in the order that the RCDLR expects, then the transmitter is out of synchronization. This occurs after 256 presses of any transmitter button when it is out of range of the vehicle

3630. Dip adapter for MFJ SWR Analyzer...need info.

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-08 03:32:00 UTC
From: Bob <bob@no-email.com>
Message-ID: <3C1189B0.98F2D6CC@no-email.com>
Source record: 153133

I picked up the a MFJ analyzer and the dip adapter with the intention of measuring the resonance frequency of the elements on a cubical quad. I have no experience with this sort of thing. I placed the dip adapter along side the element looking for a "dip" on the SWR meter. I never found one in the region I would expect to find it. Does this mean the coupling is too weak? What do I need to do to properly find the resonance frequency of the elements with this meter?

Thanks,

Bob.

Surface area would be the prime consideration. Tantalum Swiss cheese might be optimal; so too might (dare I say) some sort of fractal structure. The anvils were just a starting point (stability).

Nuclear waste would be good - it would be helpful in that it would provide ionization trails that would ensure that any stray charge on the portable ground would be drained off to your local branch circuit of the International Ground.

Perhaps an active solution is the end game for artificial (portable) grounds. You need a very small metal sphere in a shielded environment. This is the impractically small and essentially useless portable ground reference. It is connected to the reference side of an ultra-high input impedance, RF-quality wideband, high current, high voltage Op Amp. The amplifier circuit provides a virtual ground (referenced to our wimpy little ball bearing reference) that is held constant though thick and thin (even with 20 Amps of RF being dump into it). The circuit dumps the unwanted output into a somewhat larger ball bearing in a well insulated safety cage (DANGER HIGH VOLTAGE !!). The whole thing is run by rechargeable batteries. It would come with a leather case and a convenient fold down handle. An On/Off switch, a green LED and a large brass terminal labelled GROUND. $299.50 plus shipping and handling.

> Ron McConnell

I loaded up the outpost software, and I have already caught two
peckerwoods trying to break in my box in the maybe 1.5-2 hours I have
had it running. "attack detection" It's handy with the firewall as I
can see who it is, and then run a "whois" on them to narrow it down. I
was pinged on "TCP80 this morning from CA, and I was pinged about 20
min ago on TCP 1435 by some idjut at MS headquarters it seems. It
listed to : One Redmond Way Redmond, WA 98052 US
Hummmm....I think I'm going to start harrassing people that ping my
box. I'll be their worst nightmare...Whois gives me the name of the
coordinator and their e-mail etc. I think from now on, every time one
of these hackers pings me, I'm gonna shoot off an e-mail to the
offenders "coordinator" and ask why my box seems so appealing to them.
:/ I'm just lucky I manually closed all my ports months ago. They
couldn't get in even when I wasn't using a firewall, unless they knew
something real sneaky and snuck in somewhere. But I like being able to
see who it is now. MK

3633. Re: Do they make 50 ohm balanced open transmission line?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-08 05:57:38 UTC
From: tom_bruhns@agilent.com
Message-ID: <3832adca.0112072157.35602532@posting.google.com>
Source record: 153136

"One" can make such a line. As others have pointed out, it's not very practical to make a two-wire open line at 50 ohms with round wires, but there ARE other possibilities. One is to use flat (tape) conductors; then the spacing is much more reasonable. Another is to use more than two wires. A four-wire transmission line is still balanced, but the impedance is a bit lower, and you can make other multiple-wire balanced configurations which will get you to lower impedance with resaonable spacings.

Mind you, I'm not sure WHY you'd want to do it, I just know some ways it CAN be done.

Cheers,
Tom

Why would you think that that's spam? The definition of spam, as I remember it, is someone advertising something that's not appropriate. Now, if I thought I could offer something to someone that they were griping about from others, I'd probably go ahead and offer too. This guy was certainly being honest, saying that he probably wasn't the cheapest, so I don't think he was lieing. Maybe you should rethink your definition of spam?

The world is full of black boxes. Most people don't know what goes on inside them, only what comes out of them. Curious folks will look inside those black boxes and find smaller black boxes. Some will even take the time to find out what goes on inside those tiny black boxes.

But most people are only concerned with having sex and making money. To each his own, I guess.

I just wish every town had a Fry's Electronics. Then we could be complaining about their staff's lack of technical knowledge. But at least we could browse the aisles and find a 74LS4001. And pick up this month's Penthouse while waiting in the checkout line, guzzling a Strawberry-Kiwi Fruitopia...

> of them. Curious folks will look inside those black
> boxes and find smaller black boxes. Some will even
> take the time to find out what goes on inside those
> tiny black boxes.

Exactly. It only takes about four or five "Why?"s (maximum) to exhaust human knowledge...

A classic example:

Three year old son asks, "Daddy, why is the sky blue ?" (Q#1)

I reply, "It is due to the refraction of light being inversely proportional to the 4th power of the wavelength; hence blue light is scattered to a greater extent than red light. We see the scattered light from all directions and that light is predominaently blue. Thus, as is so commonly noted, the sky is blue. Okay son ? Want an ice cream ?"

Three year old, "No thanks. Daddy, why refraction of light to the 4th power ?" (Q#2)

I reply, "Son, this effect has been explained by the great physicist Richard Feynman and others in the theory of Quantum Electrodynamics. Allow me to explain..." <snip>

Three year old asks, "Why is it like that ?" (Q#3)

I explain, "It is due to the Standard Model of subatomic physics and the interaction of leptons and bosons as in your example of electrons and photons..." <snip>

Three year old asks, "Daddy, why is the Standard Model of subatomic particles like that ?" (Q#4)

I reply, "They're still working that one son. Some have theorized that it can all be explained by String Theory. Let me get back to you later..."

Three year old asks, "Gee Daddy, don't you know anything ?"

"Virtually nothing son, virtually nothing. You see, I used to work at Radio Shack..."

I need a couple 74HC02s and a 74HC11, but I'm not submitting to a
search at the door.

Tanner's is much more customer-friendly, cheaper on several items, and
they know what they're selling.

Read eg "Antennas for all locations" G6XN. or ARRL handbook (Local
library)

remove coax feeder insert a 1 turn loop of wire couple the two together
quite closely and tune for reactions. Loosen the coupling until the reaction
is quitesmall.. that will be one rsonant frequency. There will be others but
the gap between two successive frequencies will be that of the fundamental.
Check that fundamental.

Hi friends:

Thanks to everyone. The problem is solved. What was it?

The problem was due to the feeder coax, it was not centered between two pipes (it was too close to one and too far to the other), besides i had left too much, so it made a curve increasing longitud.

Having solved the problem has made me realized that this aerial is much better than a 1/4w GP. Is quite simple to assembly so i recomend it strongly.

73 72
EB5FLS

Now the SWR is like this
Mhz SWR
133 3
134 2.5

Theory shows that a vertical operated against ground is near 50 ohms
feed at about .28 or .3 wavelength. I can't remember the correct feed
arrangement. I remember I used to have a capacitor of 100 ohms
reactance at the base but can't remember if it was in series or
parallel with the feed. Can someone remind me..

Back when there was a Madison Electronics in Houston, I liked hanging out there. Personally, I liked the fact that they ignored me, and I could just browse without being hassled. But when I needed to buy something, all I had to do was ask, and they were ready to help me.

Nowadays, I buy most of my stuff from AES. I decide what I want to buy from reading the reviews in QST and CQ. By the time I'm ready to buy, I know what I want. I really don't need some retail salesman to sweettalk me or give me a pitch.

I really don't understand you guys who need some hyper, smoothie salestype to help you make your transactions of ham equipment -- but, I guess it takes all kinds.

What on Earth did you do to it? I have had one of Mel's antennas for
7 years on a 4x4 with no problems. I would imagine if you ran a bunch
of power through it you could warp the coil and that in turn would
damage the finger stock. Perhaps you could enlighten us.

I'm thinking you have an axce to grind, plain and simple.

Make a small one-turn loop using a tie wrap. Couple the "dip meter"
coil to the one-turn loop. That works for a standard dip meter.

Source record: 153152

Let me throw in my 2 cents worth to this thread:

I own all of the Valor Hamstick clones from 160 thru 6 meters, with the exception of 30M (I don't and won't work mobile CW). I run only 100W out and I have worked all sorts of dx on 20, 17, and 15 meters. I have regular 400+ mile contacts with ham friends in Kentucky and Louisiana using the 40M version also. I am very pleased with their performance from 40M up through 6M.

My theory of mobile operation is that I should reliably work the stronger stuff I hear. I, also, do not mind stopping the car and quick disconnecting one antenna and doing the reverse with another to change bands.

I use a ball mount on the rear left side of my minivan as a mount and couldn't be happier with it. The lightweight, low wind resistance Valor's do not need guying. The bigger, 160M unit does (otherwise my ball mount rotates about 10 degrees backward after my hour long one-way work commute at freeway speeds). One small piece of 20# test monofiliament fishing line tied from below the center coil to my roof rack takes care of this nicely and is virutally invisible. (Why 20# test? Strongest I could find, yet still obtrusive. WallyWorld had 250 yards of Shakespeare brand for less than 2 bucks.) On some bands (160, 75, 40, 20) a bit of shunt C clipped across the ball and ground screw on the mount is needed to secure an SWR below 1.5:1. My next planned project is to have more "learning-fun" building an UN-UN matching transformer to eliminate the need for this power wasting cap matching. (...when I develop the inclination.)

I agree that the 75M Valor is a dud. The entire whip length is devoted to being a small diameter coil and is thus very inefficient as an RF radiator. The 160M version is actually better at "getting out". While a bit weak at the other guy's receiving end, I have reliable QSO's starting about an hour after sunset near 1.900 to 1.903MHz over a 200-300 mile distance from where I am commuting from work to home, using my 100W. A low noise level on the band really helps. One cannot expect miracles in efficiency when bending the laws of physics to have an antenna that, though properly matched, is only 8% of a full 1/4 wavelength. Various ground and other R losses (in the matching coil and such) are likwise working against radiation efficiencies. Higher power would help, but using an amplifer offers its own set of added costs, and installation / operational headaches.

No matter what one does, most of the RF pumped into a 160M mobile antenna system simply becomes heat. The best radiation resistance one can expect is between 0.1 and 0.2 Ohm, compared to 34 Ohms for a "real" quarter wavelength vertical over a "perfect" groundplane. Do the math (simple division and multiply by 100) for the best case efficiency. It's not much...and that calculation is absolutely BEST CASE under non-real-world conditions. Yet, I

reliably QSO. It's both wondrous and satisfying.

I spent about $15-$17 on average for each of my Valor hamstick clones, with the exception of $70 for the 160M version. (Only Valor makes the 160M one. Lakewood does not.) Being an average ham (read: CHEAP), I won't cry too much if a low hanging branch destroys one of my antennas. I am really having a ball on HF mobile, having never done this before spring of 2001, (after 31 years of hamming). HF mobile adds a dimension to MY hobby enjoyment that VHF/UHF repeater and simplex work cannot match.

Do the Hustlers work better? (Maybe.) Is the spider top for instant and effortless bandswitching attractive? (You bet.) Is the Screwdriver a better performing antenna than my Valor's? (No doubt.) Do I care? (Not really...I'm having fun and what I have is working good enough for me. After all, this is a hobby, gentlemen.)

My fun-factor for what I've invested is paying me back in spades. Isn't that why most of us are in this??? If anyone feels the need to go further with their mobile installation than I have, please enjoy yourselves! Go do it to the full extent of your time, desire and money. Add an amplifier and a Screwdriver, if you like and can afford it. (I probably won't.)

Happy Holidays, and happy hamming everyone. Please, just remember to enjoy our HOBBY.

tony, W9MT

I wouldn't limit it to ~SWL~'s, I've
noticed that a great
majority of people use the term incorrectly.
In this particular
case, probably because it 'looks' like a
balun. I still don't
think it excuses the manufacturor for
mis-naming what they sell
If you will notice, I never said that they
didn't work, or at
least improved the match your radio 'sees'.

Source record: 153155

You'd put the cap in series from the feedline center conductor to the base of the vertical radiator, which of course is insulated from your (ground) radials; coax outer conductor to the radials. The optimum length depends on the diameter of the radiator (and how good the ground is), and the reactance of the capacitor depends also on that diameter. The free trial version of EZNEC should give you reasonable modelling results...maybe best to model it as a center-fed doublet and halve the feedpoint impedance (assuming you have a good ground); that gets the source at the right place. I think Reg Edwards has a free program that deals with verticals, too. And...I have a scanned version of some book pages with graphs that let you figure it out. But if you get reasonably close to the right length and trim the cap for min SWR, you should be fine...well under 1.5:1.

Cheers,
Tom

Jan-Matrin,
In my opinion, I don't think it's the
'best', but it is
a very nice antenna and does work. Like any
loaded antenna,
the larger the diameter of the coil, the more
efficient it
is (there really isn't enough difference to
'hear' in most
cases, though). Also, the efficiency of a
particular 'size'
coil will increase as frequency increases.
While I don't think the 'Bandspanner' is
the 'best' mobile
antenna, I would love to have one! It's a
multiband antenna
of a convenient size, that isn't as difficult
to mount as the
larger HF antennas are (or can be).

Bob-
The MFJ unit will do an excellent job, but not as a dipper. You should connect to the driven element directly, as you would drive it, and sweep the frequency. THe resonance is at the lowest SWR.
Bill-W4BSG

I also tested the tiny firewall. It's a good one too, but I liked the more advanced features of the outpost. I thought outpost may have had a leakage problem, as reported by gibson research, but I did a test, and it seems outpost is catching the outgoing data ok. "It's brings up a box asking you if you want to accept it same as tiny firewall". Tiny is very secure. No problems there...I noticed one weird thing that seems different from a year or two ago. back then , most pingers seemed to be 13 year old schoolkids in europe, etc hacking into ports. Now from what I see on ping attacks here now, it's people from big companies. :(Bad news. Since yesterday, I've had MS try twice, someone at Concentric tried. Someone at mp3 tried, someone from puter lab in china tried, etc. I'm going to keep a log of them all. It's interesting just to watch all the data fly around that you never suspected went to and fro...I also hear zone alarm is supposed to be good. Some firewalls have leakage problems. That can be tested with a small dummy exe. I got from gibson research. I'm in full stealth mode now. Before, I would show up to them, but be closed. They couldn't do anything, but they knew I was there. ". Ping me now, and I don't exist at all to the pinger. It actually slows down their hacker ping software a bit. :) MK

Craig,
I think the 'problem' is in the plate
spacing of the
capacitors, 1/16" isn't much/enough with some
of the high
voltages they has to withstand. Capacitor
plate spacing
is a large factor in the 'power' rating or
'tunning range'
of a tuner.

I used to use (and still have) Hamsticks and some Hustler resonators. I switched over to the Yaesu ATAS-100 with my FT-100. It is soooooooooooooooooo nice to be able to switch bands with a touch of a button, and top not have to get out in the weather to switch antennas!!!!

I am sure that the Hamstick perform a bit better, but I have made contact with Europe on 40M CW with this setup.

Just my two cents worth....

For both radios, I just ran the coax braid to earth and the inner to the antenna connector.

Having read all replies, I have decided to try to find baluns for both ends of the coax, and failing that, replace the coax with 300 ohm ribbon. I think I am getting a lesson in the importance of proper impedence matching...

Thanks,

w.

That's the beauty of the hobby; once in, you don't have to conform to any "performance" standards, nor do you have to jump thru anyone else's hoops to enjoy the hobby. There is
nothing to take issue with here. It's all in fun. What satisfies one may not satisfy someone else.
Now, this is my own take, and not meant to challenge anyone else. We all seem to agree that
hamsticks are not exactly the best--especially down on 75 meters. IMHO, if I am going to invest
in an antenna system to cover all HF bands on mobile, hamsticks for 80-10, at an average of
$19 each + the 160 unit @ $69.95 (I think) = around $140 +$69.95= $209 plus tax retail. So
if I am going to spend that much, why not get some performance and convenience at the same time? I am NOT challenging ANYBODY'S choices. I just elected to go the extra "mile" and spend
a few more bucks for complete flexibility, agility, not having to carry whips around, and not having
to get out in the rain to change whips or coil taps/wander leads. I have never heard of anyone losing a screwdriver, and if they are installed correctly, it won't happen. If the unit you choose is
built sturdily, they can compete with the best of trees. Oh, you might prang the whip into a "Z" con-
figuration, but you won't hurt the unit itself--------------unless, you drive under a low parking garage and hit the screwdriver unit itself hard enough. And I have another reason for rejecting the
hamsticks. I volunteer with a national emergency organization (CAP) and we sometimes have
traffic that MUST get thru. In day to day operations and in the pinch, the hamstick just won't
give the reliable performance that is needed if someone's life is in the balance. The other reason
is, well, I am just a stickler; I can't stand to have to repeat myself. I LIKE having a strong mobile
signal and I work at it. I don't have to be the loudest guy around, I just want to be heard.
And that's why I don't run hamsticks. If you ever do any field strength trials, the performance of
the hamsticks will make you sick when you see the difference.

Again, don't be mad at me: it's just my own opinion, but an opinion borne out by tests and 30
years doing radio stuff--especially mobile.

Best 73,

Jerry
K4KWH

IF the user ran power and warped the coil, then this warped coil could damage fingerstock if the
person continued to run the thing up and down. This would put pressure where it was not meant
to be and could ":snag" the fingers causing breakage. If the MW screwdriver uses PVC, then it
must be expected that you won't be able to run much over 250 watts SSB. Now if I could just
get him to look at my Carolina Cyclones. LOL! (I know, me bad, I just couldn't resist)

Mark,
Before 'harassing' the pingers too much,
you might rememeber that
all of these so called 'attacks' are fairly
normal. A simple 'ping'
actually means nothing. The particular
'type' of 'attack' can, and
does determine how 'hostile' a query is. In
most cases, an 'attack'
just doesn't mean anything.
Your right, if you've never seen the
activity that goes on in the
background it's kinda scary.
'Doc

> trials, the performance of
> the hamsticks will make you sick when you see the difference.

That's certainly true of 75m where most of the mobile shootouts are run.
One data point is -12dB for the hamstick compared to the winner which
was a bugcatcher with a large top hat. However, on 10m, the hamstick
doesn't have enough loss (compared to a bugcatcher or screwdriver)
to worry about. A 10m 1/4WL resonant whip is a little over 8ft long.
A 7 ft hamstick has very little loading and therefore, very little
loss. IMHO, hamsticks become viable mobile options at 14MHz and above.

> Again, don't be mad at me: it's just my own opinion, but an opinion borne
> out by tests and 30 years doing radio stuff--especially mobile.

Well, Jerry, you are just a youngster. I've got you by 20 years. :-)

Seriously, if you look at a plot of hamstick performance Vs screwdriver
performance 80m-10m, the hamstick starts approaching the performance
of a screwdriver on the higher frequencies. If I worked 20m exclusively,
I would chose the $20 hamstick.

Use the "map" feature on this site. Saves you alot of time in aiming the
yagis for FM and TV
stations (especially fringe stations)

I print it out and post it near my antenna rotator !

That is one of the great things about the W9INN MPD-5C is that it has
resonance on all 5 HF bands (10-15-20-40-80m) and is rated for 1500w PEP

I do not use any tuner at all after the AL-811H.....and simply use
the auto-tuner of the TS450S to touch up the match to the input circuits
of the amp...simple and very effective....

3669. Re: Feeding a .28 wavelength vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-08 19:57:06 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C127092.F8E95449@eznec.com>
Source record: 153070

It would be a series capacitor, but in my opinion you'd be as well or better off just making the antenna resonant and not bothering with a capacitor. A resonant vertical has a feedpoint resistance of about 36 ohms plus ground system loss. If you had no ground system loss at all, the SWR on a 50 ohm line when feeding a resonant vertical would be 1.4:1, which shouldn't cause trouble for any rig. Feedline loss would lower the SWR further. But I'm guessing you don't have more than 100 radials. With a more modest ground system, the ground system loss will be higher, so the SWR will be even lower. If you make the element longer and add a capacitor, you're likely to find that for your trouble, you end up with a higher SWR than you'd get with a resonant element.

Hi Mark,

Thanks for the follow-up comments on my Off Topic of Outpost. As you pointed out elsewhere, I am flying on a beta.

I've also tested my connections using the tools at Gibson:
http://grc.com/

I think my Linux box has every red flag waving with the port test (it is running barefoot - without firewall). My Windows box is invisible. Somehow I feel more secure with Linux, it is at least designed to anticipate security issues as is Java.

My first line of defense against intrusion is AT&T's unique Broadband security feature of changing complete networks.

If you look at some of my posts on this newsgroup, you will discover that I have worked in the industry. Two friends of mine owned an internationally known 800 number and walk-in ham retail business. I worked full time in their commercial division and part time in the amateur division. I've had dinner with Icom, Yaesu, Kenwood reps and Mr. MFJ himself. I know a little bit about the industry. I wouldn't own a ham radio retail business because of my knowledge of the very low profit margins and the huge volumes of equipment that must be sold. The store I worked for was a single location.

The other stores you have mentioned are multiple store chains, with the exception of Texas Towers, another single store location. Since a reasonable profit is difficult to make unless one sells a terrific amount of product, I can understand Texas Towers inability to provide super detailed and gratifying in- store service, if such is, indeed, the case.

Just because you do not like a situation, does not mean that the situation is untrue. It is a cut-throat business with little room to err. The phones ARE the business and the walk-ins are a PITA unless you move tons of equipment. As I said, I did not create this business model, nor did TT. They are the victims of it, just as are their customers.

The owners have since sold their business to one of the chains that have been previously mentioned and have reinvested their money in financial areas that do not require that they work seven days a week and put up with the typical PITA ham crowd. They even smile once in a while now. Good for them.

My Uncle Bill Schuster, owned Warren Radio in Erie, Pennsylvania, and it was eventually a considerably larger multi-outlet operation in Pennsylvania, New York and Ohio. That level of the organization, under his dominion, produced one very firm observation about counter sales he shared with me more than once. (Grin) He also finished with a SUBSTANTIAL contribution to charitable efforts, and no distribution of any assets to anyone else in the family, thank you, for which our family is terribly proud. Take a walk through the Schuster Gallery at Gannon College or the Performing Arts Center there, the Erie Philharmonic, and countless other targets of his financial affection. Uncle Bill's remark, "Heck, I've gotten so much from Gannon I have to put it back!", was dead on. You have to put it back. You have to put it back.

Thus, I too ..

>I know a little bit about the industry. I wouldn't own a ham
>radio retail business because of my knowledge of the very
>low profit margins and the huge volumes of equipment that
>must be sold. The store I worked for was a single location.

>Ed Cregger
>nm2k@arrl.net

share some of this knowledge and ... respect.

I worked within the store at this 50's and early 60's time frame. As well, my Grandafather Max was counter help in the Erie store for MANY years. He was the first person I'd ever met with tri-focal glasses! Had to have them to work with the tinsey details for parts work ... grin! Not bad for a man who came to the USA as an immigrant and whose first job was to PULL the fire engine, until they got horses for it, after which he was promoted to a pumper!

For what you say today of the below, Ed, is still today,

>Just because you do not like a situation, does not mean that
>the situation is untrue. It is a cut-throat business with
>little room to err. The phones ARE the business and the
>walk-ins are a PITA unless you move tons of equipment. As I
>said, I did not create this business model, nor did TT. They
>are the victims of it, just as are their customers.
^^^^^^^
dead on.

Even back in the 1950-60's, I can't tell you HOW many times I have been chewed out, "MIKE! If you have to take more than ten minutes with a

counter customer, we are BROKE! BROKE, Mike, BROKE! Same from my Granfather too, smile!"

The statistics on WALK-IN traffic, per the actual figures back in the 1950-60'ish arena were VERY specific! If a person who walks up to the counter takes more than TEN minutes to handle for a sale, you lose money on that sale. On average.

And, as a Novice in 1952 as WN5WQN, and at age 13, I couldn't, for the life of me, understand that, try as I might, about, in particular, the HAMS! Grin! It was too much fun to talk with them!

You see, it is our diversity as a group that makes us so intriquing as one, and to each of us within the group, is also our downfall as to profitability for those who supply us with the tools of our trade!

If WE were having to write checks or pay bills for the hourly time we spend at the target of our affection here, I betcha there'd be a somewhat different perspective about how WE shop and find favor or not with our suppliers! Heck, we get thousands of hours of service out of aa $500 rig, right? Chuckle!

But we don't write the checks for that! And further, very, very few of us ever wind up writing the checks and paying for a professional relationship with the field we, as amateur radio operators, are in. Thus we really never get to see the reason for what Uncle Bill and Grandpa kept telling me over and over again! That ten minutes used to be a pain to me, smile, but in a different way of looking at it! I was forever mad at having them cut me off from, taking time to ... Well you get the idea!

And of their point of view?

It took me a long, long time to ever get to understand that. And, now, I genuinely do understand both sides of the issue! Even at that time there was division within the professional house there! Per recall, a gentlemen by the name of Mace, split off from Warren Radio, those long and many years away, and took ... a rather substantial part of the ham radio business with him. But it too, I think, isn't strong even today, in these, the lowest level of profit margin operations, in the business. The competition is FIERCE and has VERY little bottom line margin.

You see, what we really need be thankful for, is that there still ARE the Texas Towers type of operations as well as the AEA's and all the rest. We are .. as a group, so fortunate to still have a CHOICE at all this. It takes all kinds of folks to both make us up, to deal with us. Each of us has a special unique part of us that forms our personalities and how we work with others. And they with us! There is plenty of room for all of us and, fortunately, the kind of relationship we each want in a vendor.

As you might note here ... Mikey is not part of the family electronics business either!

Huge grin!

Per Uncle, "I don't think that would ever work. You take too long with sales, Mike!" Yep! Takes all kinds doesn't it?

All this is kinda like the banker who buttonholed his account and said, "Do you know what you are doing? This is called kiting checks!" The client said, "Yes!" The banker then asked, "Well what are you going to do about it?"

The client said, "Find another bank!"

Happy holidays! Bigger toys for Bigger Boys and Girls!

All of them were either port scans or requests to connect. Some are
probably harmless pings, but I wonder about others. I had one a
little while ago tried it 4 times in a row before he gave up. This is
a list from a while ago..

12/8/01 3:22:35 PM Connection request 192.149.252.21 TCP(2431)
12/8/01 3:21:42 PM Connection request 10.10.2.105 TCP(20091)
12/8/01 3:18:17 PM Connection request 10.10.2.105 TCP(20091)
12/8/01 3:16:34 PM Connection request 10.10.2.105 TCP(20091)
12/8/01 3:14:58 PM Connection request 10.10.2.105 TCP(20091)
12/8/01 2:54:09 PM Connection request 64.12.184.57 TCP(2237)
12/8/01 2:17:52 PM Connection request 63.210.31.72 TCP(2190)
12/8/01 2:10:10 PM Port scanned 195.219.143.51 TCP(111)
12/8/01 2:09:48 PM Connection request 204.253.104.80 TCP(2148)
12/8/01 1:49:50 PM Port scanned 64.3.103.102 TCP(80)
12/8/01 1:49:46 PM Port scanned 64.3.103.102 TCP(80)
12/8/01 7:35:11 AM Connection request 208.48.67.42 TCP(1650)

I think for me to get these, it means they are actually looking for
open ports. Otherwise they wouldn't be scanning in the first place. Or
I would think anyway.
You can see that one guy did it 4 times in about 7 min time." or his
software did.." Weird...With all this I'm just glad I closed my ports
manually many months ago. Probably saved me from some port probers.
The spyware is almost worse. It's legit snoopware..

If he isn't, I am. I bought a Chevy truck, and got rid of it 3 years later. Had rust on the 'galvanized' gas tank, and also on the door hinge pin within months of purchase. Bought a Toyota car, didn't need a truck anymore. Like a rock, indeed. My brother had a Fazda (or is it a Mord) truck. Built Ford Tough alright, tough to get parts for. I basically don't even pay attention to any advertising. Most of it has some sort of untruth built into it somewhere. I can't laugh at Dilbert too much anymore, the situations are too close to life. CPA's are running companies to make money this quarter, never mind what happens down the road. Pointy-haired bosses exist everywhere. I live in a part of Illinois where owning an SUV is a status symbol, there's very little need. The nearest gravel road is at least 20 miles west of here.

NO disagreement there, Cecil.

I completely understand , but if I am going to invest in enough hamsticks to
cover everything 80-10-6 and 160, I will spend the same amount of money for
a screweriver and get the advantages
I mentioned. I never meant to imply that there was THAT much difference
on, say, 20, but
there is still some. Plus, not having to get out in the rain if my mobiling
instinct is so strong I
mean to talk regardless. You and I both know that there is no comparing the
ability to just
press a button and QSY while cruisin' down the pike at 65.

So, what happens to the resonance frequency of the driven element (determined by the above method) when you change your coax length?

Bob.

Does anyone have working knowledge of the slinky or Helitrix antenna sold by Antennas & More? Currently I am using an 11 meter vertical for 10, 12, 15 and 20 meters and would like to work 40, 80 and 160 meters also, but I have limited space. Any pro's or con's are appreciated.

Thanks,
Ron

I didn't say that you couldn't make money. I just said that
you couldn't make "enough" money for the investment and
effort required. Some people do better than others at the
same venture. Perhaps your Uncle was in business during a
different era? I too remember when everyone paid list price.
A shop could make a good living in those days.

Whatever, I'm glad he did well.

Ron,
For what it's worth, A 'slinky' would be
my last resort
for an antenna. They're 'touchy', very
inefficient, and just
not much of an antenna. Depending on your
avaiable space, there
are a number of other options for antenna
designs that I would
try first.
'Doc

Thanks for the pic. Removed the front dash bezel and looked down in the area of #2 in the pic. Lo and behold, there was a small item attached there with wires running out and heading towards the area of #1 in the pic. Popped #2 out to inspect and, voila, it appears to be the keyless entry module (at least it has an FCC ID on it, so it is some type of radio device).

Probably will revisit the dealer (or another dealer?) on Monday armed with the GIF file and the build sheet that another poster was kind enough to get from GM's computer for me. Would really like to have the factory system working.

I haave a website for the product I have developed and am now offering
in the Amateur community. Please drop by and look around.
This antenna is made especially for AO-40.
It's about time. Hu?

http://www.n3iyr.com

Thanks!

Just regitering a website with a search engine isn't always the only best
way to get the word out about a website, which he didn't actually post his.
Besides, it's not like he's mass-posting. I would hardly call a single post,
nothing fancy, no MLM and nothing outright lieing (like most spam would).
Also, just because you say it's "spam" doesn't mean it's "spam". I mean,
just because you don't want certain information doesn't mean the rest of us
don't. You're quite cynical, IMHO.

Thanks Roy.
I had a vertical like this running on the top of a natural eath mound
with a large earth mat some years ago and it worked well. I seem to
remember I shunted the base of the whip to ground with an old choke as
used on valve transmitter anodes, to bleed away static voltage.
Capacitor was a high voltage 'doorknob' type. It was virtually 1:1
SWR and 3db up on the original .25 wave vertical that was never below
1.5:1 SWR. Incidentally both were made from half wave CB aerials
(cheap) and resonated for 14.2 MHz as .25 or .28 wave verticals.
Ground mats were buried radials made from recovered lengths of old
power cable.

There's no theoretical or other reason why the extra 0.03 wavelength height would make any noticeable difference at all in field strength (see the table below), certainly not 3 dB. How did you measure the difference?

I'd like to correct my earlier posting. Going to 0.28 wavelength could make a small (although insignificant) improvement over a resonant height because the higher feedpoint resistance would improve efficiency. Let's see how much. . .

The efficiency of the resonant vertical is about 36/(36 + Rl). The efficiency of the 0.28 wavelength vertical is about 50/(50 + Rl). The following figures for ground system loss resistance as a function of the number of radials is very approximate and subject to a lot of variation, but are good for ballpark estimates. They're based on measurements made by Sevick in the '70s and included in his QST articles on short verticals.

Radials Apx Rl ohms % Efficiency dB diff.
Res. 0.28

4 29 55 63 0.6
8 18 67 74 0.4
16 9 80 85 0.3
32 5 88 91 0.2
64 2 95 96 0.1

Of course, you have add the appropriate factors for placebo effect and "appellation gain".

1) You should drill a small (perhaps 1/8" diameter) hole in the centre of the dish so that when it is aimed up during rain, it won't turn into a bird bath.
2) "Secret" feed design ? Maybe for about another two weeks until someone finally either takes one apart, figures it out, or simply has it X-rayed. It's a good sales ploy - advertising a "secret feed" on this news group. Probably sell a couple just to the curious...
3) The price is quite reasonable.
4) The "numbers" table proudly states "Polarization: LHCP, LHCP". Although the RHCP/LHCP is explained on the "better feed" page, you should simply define that the system is "RHCP".

Good luck.

It's not mass-posting?... Lessee... How many thousands of us do you think bothered to open his post looking for more info related to the thread we've been following?
Maybe you're confusing "mass posting" with "cross posting"?... The way I see it, this's MUCH worse than spamming thru email.. There, it's somewhat simple to detect spam by looking at the subject: line and delete it before reading.. When you append it to a current thread in a ng, otoh, the readers get quite a ways into it before realizing the trap they've gotten themselves into.. There's no way to unread the time you've then wasted on it...

3699. Very WIDE antennas and radials

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-09 17:16:03 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0112090916.77f7d3e6@posting.google.com>
Source record: 153102

We know from _The ARRL Antenna Book_ that a wider antenna is resonant at a lower frequency and has much less reactance (when off resonance) than a narrower antenna. A 100-foot dipole made from .001-inch diameter wire can have up to 6000 ohms of inductive or capacitive reactance. If the antenna is only .1 inches wide, the reactance is between -2700 and -2300 ohms. If the antenna is 1 inch wide, the reactance is between -1500 and 1200 ohms. If the antenna is 10 inches wide, the reactance is between -650 and 400 ohms. The radiation resistance at the resonant point near 1/4 wavelength seems similar for all of these antennas.

At 2 MHz, our 100-foot dipole antenna has a reactance of -2000 ohms if .001-inch wide, -1300 ohms if .1 inch wide, -950 ohms if 1 inch wide, and -580 ohms if 10 inches wide.

Why doesn't anyone market an ultra-wide vertical antenna? Why can't an antenna be 1 foot, 2 feet, or even 5 feet wide? While this wouldn't be appropriate for mobile use, it could be of use for home use (particularly apartments). Why is this idea the domain of just a few kooks loading up metal gutters and aluminum siding? I'm surprised the ultra-wide vertical antenna isn't more mainstream.

Just think of the benefits:
1. Tuning is MUCH easier. While ladder line losses can be kept reasonable with SWRs as high as double digits, you still want an SWR below 2 at the transceiver in order to prevent damage or lowered power output.
2. For a shortened vertical antenna (for apartment/condo dwellers), less inductive loading is needed. This would be ESPECIALLY helpful for the low-banders. Inductive loading is very lossy, very expensive, or very tricky to build. Using a wider antenna with less reactance allows one to use less inductive loading for an antenna of the same length. The right amount of capacitive loading may eliminate the need for inductive loading altogether. Another benefit: The wider vertical element provides more support for the capacitance hat, and this makes it easier to support a large capacitance hat atop the antenna. I can just picture this: A cylindrical (or rectangular) antenna that is is 3 feet wide and 7 feet tall with a set of metal capacitance hats for each band from 10m to 160m.
3. For that matter, why not extend this principle to elevated radials? I have heard that elevated vertical antennas and ground plane antennas need resonant 1/4 wavelength radials. I have heard people suggest that a Hamstick user on a 4th floor apartment add 1/4 wavelength radials. Someone using an 80m Hamstick or operating from an apartment probably doesn't have room for 66-foot radials. My

proposal: Add an area of flat metal (like my aluminum foil attic insulation ground plane)under the antenna to provide some capacitive loading. Then clamp some lengths of aluminum foil duct tape to the metal "sheet". This should provide resonant radials using MUCH less space than the conventional solution (full 1/4 wavelength wires).

My post was misleading. I was referring to the multiple hamsticks and the
Pro AM resonator for
160. A screwdrive CAN be made to work 160. Got an old #66 Bugcatcher?
Just put it between
the existing coil and the whip, or wind yourself one on another form. Some
mfrs offer 160 adapter
coils as an option.

I wouldn't think so. Thats not much of a change. I'd be surprised to
notice any real difference at all. Many use the extended verticals to
raise the maximum current point off the ground to avoid ground losses,
but you need to go towards a 3/8 wave to really do any good. I've
never heard of any only going to .28 wave for just that purpose. Like
you say, the higher radiation resistance could help, but it shouldn't
be anything close to 3 db. Normally I would think it would be nearly
unmeasurable as far as performance. MK

Source record: 153106

Theory:
"Making a dipole conductor thicker than normal, with respect to
wavelength, will increase the bandwidth and modify the working impedance of
the antenna."

Robert C. Wilson had an ARRL article on a "fat dipole" for 80/75 meters
(variation of the "cage" dipole) on page 106 of the ARRL Antenna Compendium,
Volume 2.
The dipole used 3 foot spreaders and achieved less than 2:1 SWR across the
band.

For vertical antennas, broadcast AM radio has used commercial towers (series
fed) as the vertical radiator for years.
The tower provides not only a larger/thicker element, but is required for
support at longer wavelengths (=> 160 meters) frequencies.

Yes, I do. At least Radio Shack products usually perform their
stated function. In 1999, I bought a Chevy S-10, and found
that it would often end up sitting there dead, about as useful
as a rock: http://www.km6xu.com/rnd_stf/s10woes
At least Radio Shack doesn't give one grief with defective stuff.

The difference, and it's a big one, is that you came here and opened
his email. It was delivered to you (unless you CHOOSE to download the
entire newsgroup). SPAM to email is addressed specifically to you and
it is expected you would download/read it. The way I see it, one is
targetted at you and the other you sought out. I'd say the email is
100,000 times worse.

If you have a good manual, there arent many parts you cant make somehow.
Mine works real well for long haul contacts, but not worth a darn up close.
A buddy of mine has 4 and feeds them in phase. Makes a fine array.

Hi Jason,

I am in the process of rebuilding my web site after the Excite-ATT meltdown last weekend. The work imposed is with their antiquated HTTP server that cannot cope without a restrictive file name imposition. With 740 files, many with sentence long names - this may take a while.

Anyway, I was working on this subject at the time and was in the process of publishing it:
http://home.attbi.com/~kb7qhc/antennas/verticals/Cage/cage.htm

Now, as to why no one would produce to sell this. The wire consumed here would wipe out Anaconda.

The next step would be to take these wires and spread them out cone style to lower the profile (you speak of small antennas). Another potential improvement may be found in retaining the upper disk structure and move the feed up to there. You should (if you squint your mental eye real tight) be able to see a Discone in this description. That subject is covered at:
http://www.qsl.net/kb7qhc/antenna/Discone/discone.htm

I'd second this but with reservations. I've been experimenting with 80M/160M antennas made out out of slinky elements. Slinkies don't seem to work that well as radiating elements. They're not bad as coil stock (but a bit lossy and expensive for that purpose). However one place that I have found them to be execellent is as helical ground plane elements for vertical antennas.

My back garden is only 60ft long and I thought that a slinky antenna would work well. As a comparison it's about 6-10dB down on a very bent 80M dipole shoehorned into the space. Mind you those comparisons are on receive. I haven't actually manged to raise anyone on either antenna yet. I guess 5W isn't enough with something that size.

3717. grounding question -- ideas needed

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-09 23:37:51 UTC
From: replyto@usenet.news
Message-ID: <3c13f40c.867480@news.state.mn.us>
Source record: 152970

I have the following setup:

1 2m/440 roof mounted ground plane antenna
1 backyard dipole

Both feed to the shack at the same house entry point

The roof ground plane is grounded with #6 to a ground on other side of house

I have 2 soon to be installed coax lightning arrestors for each of the antennas. Another #6 will go from outside the house entry point to a ground rod below.

Should the single point ground (inside the house) which goes outside to connect directly to the ground these lightning arrestors are connected to right outside the house(so all of them run over the same #6 wire to the ground rod), or run a separate #6 run below to the same ground rod?

The problem I see with connecting them all together is any power on the coax outside will go right in the house if I get a strike (although the center conductor will be protected). However if I keep them separate it must go to ground first.

thanks for assistance

But people do market such things. Have a look at a discone, for example. And I've seen commercial conical and biconical vertical installations. Back when aluminum was cheap, hams around the rather poor area where I grew up were fond of a vertical made from 4" diameter aluminum irrigation pipe, which you could get a 40 foot section of for under $20 as I recall (back around 1960). A whole piece of it could be loaded up fairly easily on 80/75/40/20 and 15, though it's perhaps a bit long for optimum 15 meter performance. And hams do put up cage antennas, both vertical and horizontal.

Cheers,
Tom

Bill,
If the 18-HT is the old 'Hytower' vertical, it works very
well, depending on how you install it. It requires a very
good ground system, as in lots of wire in the ground. The
better the ground system, the better it works after normal
tuning. If you find a new one you'll be very lucky!

3721. Re: Feeding a .28 wavelength vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-10 00:53:24 UTC
From: 'Doc <w5lz@icok.net>
Message-ID: <3C140776.EEFF3E9E@icok.net>
Source record: 152974

Richard,
I would think that the only reason for the additional 0.03,
or 0.05 wave length of the vertical is to provide the additional
inductive reactance needed to 'neutralize' the capacitive
reactance
you get from feeding via the capacitor ('neutralize' as in
cancelling
each other for resonance at whatever your design frequency is).
An
increase in length as small as 0.03 or 0.05 wave length isn't
gonna
make any difference in the antenna's performance.

Update about RS service. I went to the *big* city yesterday and made a special attempt to go to an electronic store that handled basic stuff, such as 12V toggle switches and twin black/red 18g connecting wire. Couldn't find this particular type of wire in numerous electric and automotive stores so I was really on the hunt. This store was open from 9:00am to 2:00pm. Get there or be square. OK, so far so good. Got there in the window of time listed above. Found a simple toggle switch that fit the bill, $6.00. Asked about the color coded twin wire to the clerk. Blank stare was the response. She then tried to show/sell me telephone 4 conductor wire. No, no no was my response. I spotted a 10ft scrap of the wire hanging on a nail in their wire department. Bingo, snatched it up and told the clerk, this is the stuff I was wanting. She said, Oh, ya, I remember now, no we haven't got any more., but you can have that scrap. Good enough for me. Later that day, I stopped by Radio Shack at the mall. Went inside and broused the wire section. Bingo, whole roll of the stuff on the shelf for $5.00. Out of curiosity, I went over to the 12v toggle switch section... Shit, exact same switch I just finished paying $6.00 for was there for $2.69. Instead of being open from 9am to 2pm, Radio Shack was open from 9am to 8pm. Hmmmmm, not to bad. They are even open on Sundays. As I was paying for the wire at RS, the clerk was doing just fine, I was thinking all along about this thread and though I would get out of there without the cellphone pitch. Almost, at the last moment she asked the cellphone question. I just smiled and said cell phone coverage hadn't made it to where I lived. She asked where and I told her. She scrunched up her nose (foiled expression) and knew I was right and said maybe someday it would get there and if so, keep her in mind. I said right, when hell freezes over, I'll be back. Was I pissed? Heavens no, it was rather amusing walking in to RS, after reading the post on this thread and putting the test on. Sure enough. Any who, I was more pleased with RS that that particular electronic repair/parts store. Was there another electronic parts store? Nooooooooo..

Richard,
Two or three years ago, Linux was probably one of the 'safest'
operating systems you could have. mainly because it was seen so
seldom, no one took the trouble to 'crack' it. You can't say
that
anymore, unfortunately. Linux is much more prevalent, now, and
the 'hackers'n'crackers' love a chalenge. If it's connected to
the internet, no matter what operating system you run, you better
look into a good antivirus program and firewall. And most
impotantly,
keep them both up to date!

Maybe because the raw stock to build such things would cost a bloody
fortune and the wind loading would be so high the first breeze to come
along would turn the whole thing to scrap?

There have been numerous articles about putting spreaders in the middle
of an element (and sometimes the ends) and stringing wire from end to end
accross the spreaders to make the effective diameter larger.

That's a bit more practical...

Jim Pennino

3731. 6 M dipole wanted

I am looking for a 6m dipole that is self supporting - either made out of a whip or small tubing. Anybody have one?

Randy

Hi Doc,

There's no doubt I've much to learn about security on the net, but security has also been one of my areas of professional design. My Linux Box is a sacrificial learning tool. The only points of exposure are my servers - the point of using a secure system like Linux instead of cripple-ware from MS.

Actually, according to grc.com tests, my WindowsME box had no need for a firewall. With some common sense options set in various utilities, I already had an air-tight system. Well, maybe a slow leak - what with the outbound MS traffic through daemon activity. I put up a firewall to simply have the logs. And, of course, snub MS.

As you might appreciate, the attackers may not be able to break the wall, but they can sure hammer the system deaf. Without the logs I wouldn't be able to separate an attack from a virus from a system failure. Anyone can write insecure applications for any system. They make the headlines - rarely does reporting get to the level of a system failure. I've seen some hoots when it came to that illusion called security.

As I started this as its own thread (what's it got to do with antennas?) - I am warning that ALL members of this board are potential targets. Myself, having a more or less fixed address, I am a surer target than those of you who connect through PPP (dial-up/modem). However, the sophistication of attack techniques now arrive not as assaults on the fortunes of your files, but being tucked away as an independently lurking program. Dial-ups have no immunity due to their

anonymity as many of these programs are DOS based(Denial Of Service). They come to life in unison to call a particular location and overwhelm its bandwidth capacity. If you come online during this "contest period" you automatically become part of the pile-ups.

Some of these programs report your activities there at your computer to a web location on the chance occasion of your connecting to the net. For my connection, that data stream would be as heavy as an ekg reading. This goes beyond cookies (I think the next generation is called muffins - more bulk). Cookies are something of a web-social contract between you and a vendor "to help you" (we know how that can go). On the other hand, there are programs that are silently downloaded to perform other choice assessment activities "to help you." And to note the season, this is more than Ol' St. Nick checking to see if you are naughty or nice.

I use the firewall in this sense as a bug zapper, where they are trying to get out. That activity far outnumbers port thumpers for me.

Both of which RS will likely keep, since all the ricer boys will buy
them for their stereos. 12V wiring stuff is a far cry from electronic
components.

Common trick in these parts for a simple TV antenna is simply encasing a
wire dipole inside some PVC pipe with a 'tee' in the middle. I recently
made one for channel 2. 6m would only be slightly longer.

Well, you see, I've been on the net a looooong time, much longer than most people have known it was around. I saw the earliest spam, and it looked nothing like this guys posting. As a matter of fact, no spam I've ever seen has ever looked like this and on topic. I think you're confusing actual spam with someone actually offering to help out the situation some instead of complaining about it. Hhhhmm..... Sound like spam? I don't think so....

RADIO HABANA CUBA
DXERS UNLIMITED

WEEKEND EDITION
SATURDAY, DECEMBER 8, 2001

By Arnie Coro CO2KK

Send your comments, questions and ideas to: arnie@radiohc.org

Hi amigos, welcome to the weekend edition of your favorite radio hobby program, our special for radioaficionados around the world! I am Arnie Coro, radio amateur CO2KK now ready to share with you today about seventeen of air time....

AND here is Item one: Another meteor shower just around the corner....remember that the very late evening and early morning hours of your local time are the best to benefit from meteor scatter propagation... Radio meteors should provide an excellent opportunity for TV and FM band Dxers to add many more stations to their logs, while amateur radio operators on the 10, 6, and 2 meter bands will enjoy yet another opportunity to work this unsual mode....

Item two: Solar activity still high enough that the ionosphere is still supporting very high daytime maximum useable frequencies, so expect more 6 meter band F2 openings during the next two to three days... So far this fall season has proven to be the best for 50 megahertz ionospheric propagation of the whole cycle 23.

Item three: Many e-mail messages received here dealing with homebrew radios, a topic that has brought a lot of attention from both regular and new Dxers Unlimited's listeners... Today, I'll continue telling you more about homebrew radio designs, and why your home built radio designed for experimenting, may outperform even very expensive commercially built receivers....

And as always at the end of the show, our HF plus 6 meters propagation update and forecast will be reaching you to help plan your operating schedule amigos!!! Margarita Delgado is my sound engineer and producer, I'll be back with you all in a few seconds...

This is the weekend edition of Dxers Unlimited reaching you during a very special weekend HF propagation, as a matter of fact, conditions are as good as any long-time short wave listener can remember amigos!!! TV DX enthusiasts should keep their VCR's rolling to pick up those very rare,

but possible, F2 layer refracted signals that are only seen during the peak of the solar cycle... YES, if you have the appropriate type of receiver, capable of receiving different TV broadcast transmission standards, it is possible to pick up TV DX that reaches your set not via the typical sporadic E mode, but via the much longer range F2 single or multiple hop modes. Imagine watching Australian low band TV in the Caribbean, or picking up a New Zealand TV station in Buenos Aires, well all this is possible when the F2 MUF goes above 45 megaHertz and higher!!!

Don't forget to keep a log of your TV DX and make at least one copy of those unique VCR tapes whenever you happen to be lucky enough to pick up one of those elusive F2 TV DX openings. And, please do share your experiences with the worldwide audience of Dxers Unlimited by sending your comments about the F2 TV DX openings e-mail to arnie@radiohc.org or via FAX to the following number 53-7-705810....

Now here is item three of today's edition of Dxers Unlimited... more about homebrew radios: Well, amigos, it's nice to see that this topic has generated such a great interest and also to realize how creative our listeners are.... I want to say again that I have received several very interesting e-mail messages about the power supply and the front end of the SUPER REGENERODYNE homebrew radio, and some of them are really funny... like the listener who said, "Arnie why attempt to build a NEW receiver using vacuum tubes for the front end?" so I decided to answer both, directly to him via e-mail and now on the air...

Amigo, if you happen to live in a part of the world where thunderstorms are frequent, as we do here in the Caribbean, then you will know why many radio amateurs have lost not one, but two or three or more times their front end amplifier devices... MOSFET's are particularly delicate electronic components, no matter how you try to provide protection for them... And there are two radio frequency amplifier circuits that perform at least as well as the best MOSFET in the frequency range from the Low Frequency bands all the way up to the 50 megaHertz, amigos. One is the standard classic pentode RF amplifier stage, and the other one, that I like best, is the cascode, using dual triodes or a pair of individual triodes.

Well, again, I want to tell you that there was another e-mail that came in from a Dxers Unlimited's fan that told me that he had already built a better supply than the one I described, because his supply uses a fully electronically variable and regulated high voltage power unit, using a technology that was very popular during the nineteen-fifties at the microwave radio relay systems sites... To all of you interested in homebrewing your own radio gear I just want to say something... there is nothing like operating a radio set that you have built yourself, no matter if it is a single transistor crystal set plus audio amplifier, or a sophisticated dual or triple conversion receiver!!!

Now, let's move ahead with today's description of the DREAM RADIO's detector stages, that are capable of receiving AM, CW,SSB and Narrow Band FM signals... After testing many different regenerative detector circuits,

I decided to settle with the very easy to design, assemble and operate Hartley type classic triode detector, which uses a cathode tap to the grid coil in order to provide the required feedback to make the detector operate. My other choice is the use of a small tetrode or pentode vacuum tube that provides the advantage of easily controlling the gain of the detector stage by changing the tube's screen voltage...

The DREAM radio has the possibility of choosing from up to four different detectors, a standard AM envelope detector using a vacuum tube diode, a detector using a triode connected as an infinite impedance configuration, a regenerative detector and, last but not least, a classic discriminator type FM detector...

Yes, I agree that this adds one more switch control to play with, but please realize that this is an experimental receiver, a radio that provides a lot of enjoyment to the operator by playing around with the careful adjustment of its operating parameters!!!

The Hartley regenerative detector has an amazing sensitivity and stability, and it operates even with extremely low plate and screen voltages. By the way, both plate and screen voltages are regulated, adding to the stability of the circuit, that can be taken very, very near to the point of oscillation, where the Q of the tuned circuit is extremely high, and kept there to provide razor-sharp selectivity when receiving CW Morse Code Signals. As regulated voltage is available, the infinite impedance triode detector is also fed from the regulator, but of course the diode detectors do not require plate voltage to operate!!!

More about the DREAM RADIO's different detectors after this short musical interval... Amigos you are listening to the weekend edition of Dxers Unlimited, you can send your signal reports an comments via e-mail to arnie@radiohc.org and Via AIR MAIL, a postcard will be fine, to Arnie Coro, RADIO HAVANA CUBA, HAVANA, CUBA.

Now, more about the detector stages used in my DREAM RADIO EXPERIMENTAL MODULAR RECEIVER!!! The detector stages are all fully enclosed in a shielded compartment, with the plug in coils properly spaced away from the walls of the compartment so that the Q or factor of merit of the coils won't be degraded by the proximity of the metal shield... The coils were designed for the highest possible Q, and I have wound them in both very high quality ceramic coil forms and easy to work with PVC drain pipe coil forms, without really noticing any difference in operation between the two types of coil forms, at least in the range from 500 kiloHertz all the way up to 10 megaHertz...

Anyway, as you have heard or read, the SUPER REGENERODYNE'S detector stage normally operates in the range from 2 to 4 megaHertz or near to this frequency range... The idea of covering just 2 megaHertz per band is to provide a very good calibration that holds for each of the bands, as the crystal-controlled front end simply mixes the incoming signals from the antenna down to the 2 to 4 megaHertz range... In other words, your regenerative detector is always tuned from 2 to 4 megaHertz.... In my

DREAM RADIO, I do not use a crystal-controlled front end all the time; that is, I can change from the crystal-controlled oscillator to a variable frequency oscillator, something that must be done so that FM reception is possible... In other words, the FM discriminator type detector operates at a fixed frequency of 4.5 megaHertz that was chosen because of the easy availability of 4.5 megaHertz TV sound intermediate frequency amplifier transformers, so you do need to do the tuning by changing the frequency of the front end's local oscillator.

As I have said here at Dxers Unlimited many times, regenerative receivers are ideal for homebrewing and their tolerance for parts values is outstanding.., but combining conventional super-heterodyne technology with a regenerative detector stage is a really nice approach to homebrewing a sensitive and low-cost radio. But the DREAM RADIO was not thought as a low-cost project, as anyone attempting to build his or her own version of the DREAM RADIO will be willing to spend quite some time and shopping around for the specialized components required for the project.

Next Tuesday and Wednesday UTC days, during our regular mid-week edition of this show, I will continue describing my DREAM RADIO -- another hybrid receiver that uses both solid state and vacuum tube components to achieve outstanding performance while keeping things rather simple and easy to assemble, even for old timers who have a hard time working with miniature electronic devices!!! Because in these designs absolutely no attempt was made to miniaturize the receiver and modular construction was used, so that a lot of experimenting can be done without spoiling already fully operational, well-tried and proven modules...those that you want to keep intact after all the experiments.

Well amigos, I hope you are enjoying this step-by-step description of my latest radio receiver project, one that has drawn from the experience of many enthusiastic radio experimenters around the world who have made the wonderful gesture of sharing with all of us the results of hundreds of hours of hard work.... And as a local radio amateur here in Havana told me a few days ago, one can start building a simple power supply and a regenerative receiver for the 80 and 40 meter bands, that is also capable of tuning the very popular 6 megaHertz international short wave broadcast band, using recycled components to keep the cost of the project pretty low... Also, these radios are ideal for showing at the radio club's meetings and keeping one right next to your store-bought, professionally built receiver will not only help you realize the amazing sensitivity that they have and their razor-sharp selectivity when properly adjusted, but also will provide that additional radio that is so nice to have when chasing for DX without losing the broadcast time of your favorite radio hobby program!!! Without forgetting the fact that the basic receiver will work nicely as the TAIL END of a nice front end converter!!!

And now amigos, as always at the end of the show here is Arnie Coro's Dxers Unlimited's HF plus 6 meters propagation update and forecast... Solar activity will probably go below the 200 solar flux units mark very shortly, but the ionosphere is in such a healthy state that very high

daytime maximum useable frequencies are going to continue happening during the next several days....

Ten meters was open Friday from shortly before sunrise here in Havana to hours after sunset. Now scientists are talking about a second peak of cycle 23, something will equate this cycle with cycle 21 for its level of activity... Expect very nice propagation conditions on an almost round the clock basis this week, and don't forget to at least monitor an empty FM broadcast band channel during the upcoming Meteor Shower. You can leave the tape recorder rolling and then come back from your visual observations of the shooting stars... The same holds for an empty VHF low band TV channel if you are fortunate to have one in your locality, just leave the VCR running.

Attention 6 meter band operators, this is a special advisory for YOU!!! Chances of worldwide 6 meter openings are very good both on Sunday December 9th and Monday December 10th, so be on the alert looking for those nice DX stations that are populating 6 meters nowadays!!!

And don't forget to send me your signal reports, radio hobby related questions and comments about the show to arnie@radiohc.org or VIA AIR MAIL, a postcard will be OK, to Arnie Coro, Radio Havana Cuba Havana, Cuba.

Probably very true. Then the *big city*, to me, doesn't have squat as far
as electronic components. Lesson for me then is to go to RS first and if
it isn't there, skip the rest of the town, surrounding towns within the
state and so forth. Hope for a mail order place.

I think the spyware such as doubleclick, etc is about #1 on my list.
I'm trying to learn about running this firewall to make sure I'm
properly blocking it all. That why I wanted to make sure I'm not
leaking outbound. It's kind of confusing because I'm supposably
supposed to be blocking most of it , as far as cookies, pop-up's etc,
but I keep seeing hits in my DNS cache table. So I'm not sure if those
are hits that have been blocked, or if I'm still actually talking to
them under the table. Note this dns log...

12/10/01 6:07:16 AM www.google.com Cache hit 216.239.35.101
12/10/01 6:07:15 AM posting.google.com Cache hit 216.239.35.122
12/10/01 5:50:42 AM groups.google.com Cache hit 216.239.35.119
12/10/01 5:37:28 AM grc.com Cache hit 207.71.92.193
12/10/01 5:19:27 AM m.doubleclick.net Cache hit 208.184.29.190
12/10/01 5:19:26 AM ehg.hitbox.com Cache hit 209.75.22.238
12/10/01 5:19:26 AM ad.doubleclick.net Cache hit 204.253.104.80
12/10/01 5:19:25 AM a1604.g.akamai.net Cache hit 216.119.141.232,
216.119.141.231
12/10/01 5:03:10 AM grc.com Cache hit 207.71.92.193

You can see I was at GRC.com and then went to google. Notice all the
"spyware" hits from doubleclick and hitbox, etc. What I want to do is
totally block it out so none gets in, and none can call home from
within. I'm not sure if those cache hits are from blocked stuff, or if
it's still talking to them in some way.
My active content shows a blocked activeX object on the first load
earlier, but it didn't show anything blocked on the cache hit later.
Being I am picking up no
cookies, I don't see how they could do anything, but I worry about my
registry data. I believe doubleclick reads registry data to profile
computers, but I thought they needed the cookies installed to do
it..?? I'll have to look into that more.

>
> I use the firewall in this sense as a bug zapper, where they are
> trying to get out. That activity far outnumbers port thumpers for me.

Yep, it's the outbound I'm most worried about. I've been fairly safe inbound even before using the firewall just from having all my ports closed manually.
But I would still pick up all the cookies from doubleclick , etc if I enabled cookies. What I want to do, it try to train this firewall to accept cookies that I say are ok, but block all the rest. It will probably do it, I just need to learn how to set it up. Probably about half the port probes are benign. But the other half...you never know. I've had these thumps in the last 24 hours, with only off and on dial up. Wasn't on all the time.

OFF TOPIC - sorry...

"Mark Keith" and "Richard Clark" were discussing PC security...

http://www.zonelabs.com/zap26_za_grid.html - Free (and very good) software firewall. Seems to be 'the standard'. The free version is hardly a compromise - it works great. Mine blocks dozens of Internet noise every hour.

http://www.lavasoftusa.com/index.html - Free (and very good) spyware removal tool called Ad-aware. (Be sure to get the RefUpdate automatic update tool as well.) You'll be amazed at the sort of junk that lurks in your system if you have never checked before.

http://www.ontrack.com/internetcleanup/ - Not so free Internet Cleanup tool. Now at version 2. Mine is version 1.04.6 and just happened to be 'free after rebate' at a big retail outlet (which actually arrived after a few weeks). You have to be careful not to go overboard deleting cookies, otherwise you'll suddenly have to try to remember all those passwords to access various sites. Basically, you delete the 'evil' cookies and keep the 'friendly' cookies. Where you draw the line is up to you.

There are plenty of other choices. For freeware - see www.NONAGS.com.

All of the above tools will deal with 'doubleclick' cookies. Ad-aware and Internet Cleanup simply delete them. There are plenty of other 'broadcasting' and 'projecting' spyware applications.

Warning - downloading, configuring and running the above tools will take most of an evening (depending on how much junk is in your system). Don't start this 10 minutes before supper time - there is a fair amount of effort in configuring and getting started (especially with Zone Alarm which is quite talkative at the beginning, but settles down after a while).

SORRY TO BE OFF TOPIC.

Jason:

These types of antennas, usually referred to as cage monopoles have been in production for over 40 years. If you're interested, I'll go through my photo collection and send some shots of these types of antennas made for military HF applications.

I agree with you on the Bug-catchers, Doc. I didn't say what kind of performance one should expect with either one. I was merely pointing out that when comparing antennas, one should compare antennas intended for similar installations. Comparing a mobile antenna to a fixed 1/4 wave antenna makes no sense at all.

I am director of marketing for an autoparts wholesaler where we have two T-1's and about 30 phone sales people. We have about 6 counter people. It is a continual battle for us to weigh calls against walk-in trade; however, there are huge benefits to having sales people deal face-to-face with walk-in traffic, least of which is that of having a training ground.

Not only do I train newbies on our counter, but I also require each phone salesperson to get up off of his butt a few hours each week to meet customers face-to-face It is far too easy for phone sales people to forget who they are dealing with. Far too often I hear, "What's your account number?" Or, "okay", instead of 'Thank you for the order'. We've all been there, and we know when we have a grumpy phone sales person on the other end of the phone. By having a counter area at least the sales people are reminded of who they are dealing with. The experience carries over to the phone bank.

I won't even get into the times the counter saved us because UPS went on strike, or the times the customers saved us shipping expenses. (I've often thought about discounting freight costs to the customers if they picked up their order)

Interesting. How well does it perform on 20?

I have an 11 meter vertical that was trimmed down to work on 10m, planned to use at field day this year. Would be nice if it could do 20 as well, so could work better through the night.

I'm not really worried about those too much. They can't get in anyway
even before I ran a firewall. Like you say many are benign so you
would need to watch one for a while , and also note the ports used
etc. All the different ports are used for different things in general,
and are fairly standardized. Or at least the main lower ones anyway. I
have lists of the ports used by most of the common bugs and trojans ,
so can get an idea if one might be real. Like I said in another post,
I'm much more worried about what goes out ,than comes in.
I don't like them getting my registry data, etc with the spyware. MK

Try your nearest hardware store. They usually sell the aluminum tubing (not at the cheapest price you'll find, but reasonable). My Sears Hardware has a good supply. They have 1/2 inch 6061 in stock.

This is a case of comparing apples to oranges, Alan.

How many auto parts customers expect you to remove a carb from the box, hook it up to an engine and run it, just to see how it works? It's pretty common for a prospective customer of a ham radio to expect a ham dealer to hook up a rig to an antenna and let them play for a while. Is the rig still "new" after such a session? Remember, not every ham retailer is large enough to have several demo radios hooked up for customer try-outs.

Ed,

They are not all that different. Go to any retail auto parts store on any given day and you will overhear, "but, it makes this funny clicking noise...", or, "it only shuts off only when the engine heats up or once I get going down the highway...".

I like the carburetor analogy, ever try to sell one of THOSE things to a customer who refuses to give you the tag number? Phew!

I don't deny lines have to be drawn. For instance, I don't allow my salespeople to leave the building, otherwise some of them would be out in the parking lot this minute trying to diagnose engine problems. I do, however, expect my sales people to be attentive, courteous, and kind. They don't have to climb under the hood, likewise, I wouldn't expect a clerk at a Ham Radio store to tell me why I can't load up my amplifier. In your example, I wouldn't expect a clerk to hook up a new radio either. It would be a bonus if the retailer had a facsimile set up.

All a good sales person has to do is show a little respect 90% of the time. It sounded like the original poster of this thread wasn't even shown that.

Alan

Boy, I really don't see that. And I have been buying from the majors, like Henry Radio since the late 40's. Personally, I do a lot of research on a rig before I buy it. When I am ready, I walk in (or on-line now), plunk down the money, and walk out with it. I'm sure some people insist on seeing it work first, but that's not the norm in the western part of the country. Can you imagine if everyone at Dayton, or even a local swap meet wanted a demo before purchase? I don't think so.

I'm afraid I have to agree with Doug and Jeff. I went in there a
couple of years ago (actually drove all the way from Houston) looking
for a tower mast. I had to hunt down someone to talk to and I was the
only customer there. Felt like I was invisible. My last visit to TT.

As a person who now makes my living selling merchandise largely to amateurs, I've been watching this thread with some interest. I'd like to add just a couple of thoughts.

The first is what I consider to be one of the really basic principles of doing business, but one that so many businesses just don't seem to get, and it's this: You don't have to make money on each sale. You just have to make money on the average. It's amazing how different your attitude is to customers when you understand this simple principle. A person posted earlier that his boss determined that they'd lose money if more than an average of ten minutes was spent on each customer, and used it to justify a rule that no more than ten minutes was to be spent on any customer. That's an example of a company that thinks it's necessary to make money on every sale. If you're going to treat your customers right, you've got to lose money on some sales. If you or your business can't handle that, then I think you're in the wrong business.

The second is something I was told many years ago by one of the principals at Portland Radio, the last of the local old-style radio stores in this area. At that time, the store was nearly empty of customers and very obviously on its way out, after decades of success. His explanation for the death of the walk-in stores was one that really sunk in. He explained that people would come into the store, get time-consuming demonstrations of all the various rigs, try them out, ask questions, then leave, go home, and buy the one they wanted by mail order because it would save them money. In fact, just the other day I picked up a magazine about digital cameras, and that's exactly what the writer suggested doing!

The people have spoken. They want, above all, low prices, and place their orders wherever the prices are lowest. The only way any store can compete is to drop prices to the level of the mail order and web sellers, and the only way to do that is to have comparable labor costs. Then the very people who chose price over service complain about the lack of service. Sorry, folks, you can't have it both ways.

Interesting question. If the carburetor cost $3,000 (like a transceiver), and there were three brands to choose from, and there were definite and known operational differences, and it could be hooked up in five minutes, I suspect that just about everyone would want to try it out before buying. Continuing the auto related analogy, how many folks would shell out even $3,000 for a used car without being able to try it out? And, ever see a new car dealer who didn't have demo cars to drive? From the prices ham dealers charge for their "demo" used equipment, I doubt that they're losing money on those.

Same observation here. What I have considered as a solution for the manufacturers and their dealers, is some kind of "coupon" offered at the walk-in store for each potential sale. The coupon would be "store specific", that is, it would identify the dealer who actually "made the sale" by demonstrating the equipment versus the dealer who actually shipped the product. Give the customer a slight discount at the time of purchase, when he uses the coupon at another dealer the manufacturer should credit the store which did the actual "selling" of the product, a commission split with the selling dealer. This would encourage dealers to SELL equipment instead of just stocking boxes of units which must be moved. The customer benefits by getting better availability of demo gear, the local dealer would receive income regardless of whether the unit was stocked and sold locally or not, and the big mail order dealers would profit by increased sales, although on a lesser margin.

LOLOLOL-

I know it's off topic, But-

I had a Customer come up to the Counter of a Parts Store where I worked.

(me)- "May I help you, Sir?"

(he)- "I want a Set of Plugs for My Car"

(me)- "What Make and Year"

(he)- "1991 Chevy"

(me)- "What Size Engine?"

(he)- "Ummmm, I have no idea"

(me)- "Is it a 6-Cyl, or V-8?"

(he)- "I have no idea at all-"

(me)- "Is your Car here in the Parking Lot?"

(he)- "No, it's at Home- I drove my Wife's car today to have it washed-"

3759. TRILECTRIC A25100U UHF BRICK

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-11 00:23:24 UTC
From: nedrog@aol.comNOSPAM
Message-ID: <20011210192324.05898.00000340@mb-fx.aol.com>
Source record: 153012

Looking for information on a TRILECTRIC A25100U UHF BRICK. Trilectric is a division of CELLTRONICS, INC.???

Any information would be greatly appreciated, ie: SCHMATIC, OPERATORS GUIDE, ETC.

TIA

HOWARD
W3CQH

Arnie,

Fascinating stuff, especially on the homebrew "regenerodyne" receiver and the TV DX F2 possibilities. I know from watching this newsgroup (rec.radio.shortwave) you have a lot of fans who enjoy your show. As far as I know, your show is unique among major SWL broadcasters by going into a level of technical detail and into ham topics that other shows shy away from. Rest assured there's a contingent of fans here who really enjoy your show's approach.

As I've remarked in the past, a lot of us think you could put together a working radio from a cardboard box, some wet twine, a razor blade, and candle wax. :)
It's refreshing in this day of "plug and play black boxes" that some still understand that part of the fun of radio is building your own, and understanding how it all works.

Speaking of static and lightning resistance of tubes, I would imagine Cuba has quite loud thunderstorm static during the summer months. Have you done any experiments with tuned loop antennas for HF receiving, especially in the higher HF range which is traditionally not thought of as a good place to use loop antennas? It would seem such a design would provide some protection against static and could perhaps null out some local lightning noise, giving a signal-to-noise ratio advantage?

73, and thanks for posting!

Roy, as usual you are quite correct. All that's necessary to obtain SWR = 1-to-1 on the 50-ohm coaxial feedline to a 1/4-wave vertical is to discard, one by one, most of the 120 Marzipan magic number of buried radials until the SWR meter remains on the left-hand stop. A fully-fledged tuner is not needed - just a variable 500pF low-voltage capacitor.

In any Z-matching R+jX system, as a fundamental principle, two adjustable knobs are needed, one for R and another for jX, Knob 1 (R) is the 120-position rotary switch which selects the number of radials. Knob 2 (jX) is the variable capacitor.

Do you think this subject should be a candidate for articles in the next edition of the ARRL and RSGB Handbooks ? ;o) ;o)

Child? Child my a$$. Maybe compared to an old f@rt like you, yeah, probably.

> Why does everyone who winds up on the loosing side of any argument
> concerning the internet ALWAYS resort to this "I was on the interney WAY
> back when..." crap?...

Because, maybe those of us who HAVE been around computers a long time know a thing or two. I was programming original programs by the age of 9 and wrote my first graphical webpage when I was about 15, using notepad and Paint Shop 1.2 (I'm 27 now).

> Because you actually think anyone believes it?

No, because it's true. But you don't want to know the truths because you already seem to know it all. Well, as much as an immature 13 year old anyway.

> Sure, give us a few dates, and maybe even a school or company name in your
> next posting..

Ok, well, the first public access was Freenets, UNIX tty interface. We didn't have any around here so it was long distance. I think it was around '88 or '89 or so. Sure, BBS's were cool, but this was great because you could "talk" to all sorts of people telnet from one account to another. I only had a 2400, so transfers took a while. I had several accounts around the U.S. at several Universities, so sorry I can't remember all those schools. The first local public access didn't show up for about 3 or 4 years, and then it was using Windoze 3.1 with the Winsock dialup software. H*ll, I beta tested AOL's "Internet" services (Hahahahaha.... what a piece of crap) So, yeah, I have been around the 'net a long time. How long have you been online?

> H*ll.. I *invented* the internet... How's that?...

That's a load of B.S.. The inventer of the Internet's initials are not BD. Now who's tellin' stories?

> Spam is still SPAM...

Like I say, it depends on your preceptions and your definition of spam.

Source record: 152919

The important thing is not the SWR but how far can you work ? 1000 yards ? 1000 miles ?

How is SWR related to distance ? Nobody, not even the old wives know !

Far too many people are completely, psychotically obsessed with SWR. Voices are heard. Insistent voices..

They who hear voices are simple, innocent, childish, victims of SWR meter, antenna and antenna-tuner manufacturers' sales waffle and baffle-gab, not to mention deliberate untruths, distortions, lies and brain-washings.

It is a fact your SWR meters don't even measure SWR. Where is the transmission line on which the SWR is measured ?

With the growing world population there are many born every minute. ;o)

> won't see the effect of that amount as it wants to play like a narrow
> coil of sorts. MK

Reading that, doesn't make sense in a way. What I've noticed when turning back unisulated wire is it wants to act longer than the "measured" part up to the insulator. I've noticed this many times on quick "out in the boonies" dipole setups where I make the dipole from scratch. If you turn back a foot of uninsulated wire, it's quite precise as long as you wrap the wire back tightly to make it look like a single wire. But with the insulated, I can turn back a foot of wire and even coil it back real tight, and it acts a bit longer than normal. So I've found with that if I'm really a good bit long I have to actually trim the wire or I'll have to coil so much wire back it's kind of silly. I'd rather just cut it off. Small amounts are no problem usually, but you will usually need to turn back a tad more of insulated compared to uninsulated usually. Uninsulated is pretty precise in comparison. MK

Source record: 152928

You're welcome, Ken. My email is K1VY@arrl.net

I just went through the same stuff on my A4S, and I learned quite a bit in the process. Cushcraft should be chastised (again) for ignoring the rules of galvanic reactions, virtually every A3 and A4 (and others too) are essentially little time bombs ready to go off.

By the way, I recently learned of a product called Penetrox, by Burndy, that apparently should be spread on the contacts prior to assembly. The claims are that it prevents or at least greatly inhibits the galvanic corrosion.

Good luck with yours, hopefully mine is set for the winter anyway...

Neil

Advance, I think it was, used to make such a relay, so one might turn up at a swapfest. In the meanwhile, you need a couple of ceramic insulated relays with low capacitance between the contacts and the coil or mounting. The latter can be accommodated with appropriate mounting on insulators, and the former with RF chokes in the wiring to the coils. Mount them the appropriate distance apart for 450 ohms, and have at it. There were some surplus relays which fit this application also, IIRC.

Source record: 152929

Barry,
There are a number of ways you could use a relay for switching ladder line. If you have two relays, this may be an alternative. Using D.P.S.T relays, connect the ladderline to each 'studio' to the common poles. The 'N.O.' pole to the incomming ladderline, and the 'N.C.' poles to ground. When one of the relays is activated, the studio is connected to the ladderline. When not activated, the 'studio' is grounded.
With just a single 'D.P.S.T.' relay, one 'studio' would be connected all the time, the other 'studio' when the relay is activated.
These are just two arrangements, I'm sure you can think of several more. Just depends on which way you would rather do it...
'Doc

('N.O.' means normally open. 'N.C.' means normally closed.)

Source record: 152933

Mark Keith, NM5K wrpte:
"But with the insulated (wire), I can turn back a foot of wire and even coil it back real tight, and it acts a bit longer than normal."

I speculate the cause may be that bare wire looped through an insulator and twisted around itself at the end of an antenna makes contact. Through the contact, two paths are formed to the antenna`s end. Inductance is reduced.

When insulation prevents contact of the twisted wire, the inductance of the wire is largely preserved. As Mark says, "---you will usually need to turn back a tad more of insulated compared to uninsulated---."

Best regards, Richard Harrison, KB5WZI

Good one Jim.
Also here is a web site that gives distance and bearing from your QTH to
all DXCC entities plus more:
http://mdxa.org/dxcclist.html
By Randy, W5UE

Returns Prefix, Country, Short Path Bearing, Long Path Bearing, Miles,
Latitude, Longitude, Continent, CQ Zone.

You will need to enter your Latitude and Longitude (GPS if you have it) or
you can find it at http://www.qrz.com/
At QRZ -- Enter your call then click on detailed info to obtain a good
approximation of your long - lat.

Much more on Beam Headings, Distance, Bearing, etc at URL:
http://ac6v.com/opaids.htm#BEAR

Sure, and the internet will enhance the trend. We have self-service fuel stations and U-Plumb-It stores.

"Consumer Reports" magazine gives fair comparitive evaluation reports on different makes and models of high-volume goods. Equipment reviews in Ham magazines are not in the same league with "Consumer Reports". They should be.

Unfortunately, few reviews rank competing equipment or recommend best buys with carefully considered reasons given as to why. Too often, a review is written by, or heavily influenced by, a vendor of a single brand. How many times have you seen a write-up saying this ham product is completely unacceptable?

Honest and informed consumer reports for ham gear are really needed as there is little opportunity or ability of many ham purchasers to try or evaluate ham gear.

Best regards, Richard Harrison, KB5WZI

In the pursuit of sneakyness, stealth, and the american way, I ran
across a super easy way to zap most spyware or anything at all for
that matter. The trick? A host file. Using the host file, you can lock
out anything you want with nothing else attached. So you could just
manually close the ports, and then block sites with the host file, and
pretty much kill the whole problem without having to use a firewall.
I'll keep the firewall though to detect new ones and be able to get
the address. I just started running one here, and it's working well so
far. With it running, at sites with spyware, I now get a "can't
connect" tab for the spyware that pops up, and I just click through
it. So now, it's totally history here I think. My computer now refuses
to talk to them at all. You can dial up www.doubleclick.com as a test
and it will cancel out. I'm using a host file with an entry for every
known spyware on the planet. If I see a new one in the firewall, I can
just add it to the host file and it's history. So anyway, I'm now
doing what I set out to do...Kill the stuff in it's tracks. For info
on using a host file and how it works etc , and usable "sample host
files" with all the entries, you can go here.

Why not get a bunch of hams to write in to ePinions.com and push the
idea of adding a ham equipment section there? Bad reviews are given
just as much weight as good ones, and the rating system accounts for
them as well.

The finest Christmas story ever written is mid-19th century, victorian Charles Dickens' "A Christmas Carol".

Read how the wicked miser, slave-driving Ebenezer Scrooge is haunted in his dreams on Christmas Eve by a succession of ghosts, Christmas Past, Christmas Present and Christmas to Come, and wakes up on Christmas morning a completely reformed character.

A story for both children and grown-ups. Dickens can make you laugh one minute and cry at the next.

There is a film, black and white, which fairly faithfully follows Dickens' story. Scrooge is played by that great serious and humorous actor Alistair Sims. All TV stations should broadcast this film on Xmas Day afternoon while the more affluent watchers are digesting their dinners washed down with port wine.

But the relatively short story is best.

Ebenezer opens his house window to the busy London street and cries "Boy, yes you boy, what day is this ?"

A lot of the lightning energy will still follow the coax as a path to
ground, the coax braid represents a very low impedance path.

I'd bring the arrestors to a single point ground outside of the house,
right at the ground rod, to provide lightning protection. You don't
want to provide a path for lightning that must pass through your
home to find ground.

> The problem I see with connecting them all together is any power on
> the coax outside will go right in the house if I get a strike
> (although the center conductor will be protected). However if I keep

Don't count on the arrestors for center conductor protection. If your
arrestor is designed to pass 1-kW RF to the dipole, it will certainly
allow a bilateral 1-kW amount of lightning induced RF
energy BACK into your
receiver.

Always using a shorting coaxial switch or disconnect
the station coaxes when not in use.

3790. Do "folded" folded dipoles work?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-11 20:26:27 UTC
From: tek_guy@hotmail.com
Message-ID: <cbf4a67d.0112111226.68bb32fa@posting.google.com>
Source record: 152942

I saw an article in a back issue of Monitoring Times about improving the directionality of the 300-ohm TV twinlead folded dipole for FM reception by mounting the antenna on a 29 inch piece of wood stock, and folding the elements back so the entire assembly is folded on itself.

I thought that by folding parts of a dipole back in on itself, signal cancellation occurs, and the results aren't that great. Does folding folded dipole elements negatively affect the performance of the antenna?

Thanks for any help in advance.

A folded dipole has the same directional pattern as a simple dipole. So you could easily see what the effect of bending one is by using any of the current modeling programs. You can get the free demo version of EZNEC at http://eznec.com. It would be adequate for this purpose.

Bending any antenna doesn't make energy disappear by "cancelling the signal". All the power applied to an antenna has to be either radiated or dissipated as heat, and its receive properties are the same as its transmit properties. The W8JK antenna is an example of an antenna in which the fields from the elements partially or fully cancel in all directions, yet produces gain relative to a single element. It's one of the example antennas furnished with EZNEC.

3802. advice needed on crystals for heathkit dx-60

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-12 00:37:47 UTC
From: paper342@yahoo.com
Message-ID: <vFxR7.13$YE4.3887@newshog.newsread.com>
Source record: 152955

Hi,

I am in the process of purchasing a heathkit dx-60 for my fiancee's son. It's his xmas present. Anyway, he's got his novice license, and the plan is for him to be able to xmit cw on the 40 meter band. Currently he has a mfj 1040 rig, but he's studying for his tech plus and possibly even his general license.

I know a bit about Ham and radio, but haven't gotten a license yet myself. Anyway, I'll need to get some crystals for this rig. I talked to a few people... one person said he thinks the sockets might be hc-17/u sockets. Is that correct?

I think I read once that transmitters don't necessarily transmit on the frequency on the crystal. Instead they often use a multiplier or something on the crystal. Can someone clear this up for me? What frequencies are pretty popular in the 40 meter band and how do I do the math to calculate the actual frequency being transmitted on based on the crystal, or is the frequency of the crystal I stick in the socket going to be the frequency I am xmitting on?

Also, can someone verify for me what kind of crystals I need for the sockets in the Heathkit dx-60? I'm aware that we could track down a vfo somewhere, but the crystal idea just seems neat for some reason, sorta a making do with minimal equipment.

Please cc responses to paper342@yahoo.com so I don't miss any

Thanks

Jim,
The crystal holder is an FT-243, and for 80 or 40 meters
the crystal is cut for the primary frequency (no doubling or
tripling). You might also consider the 'VFO-10' VFO for the
DX-60. Much cheaper in the long run than crystals, even if
it does drift.
Unless you got a super deal on the DX-60 (like free), I
would hesitate to recomend one for a new ham. It isn't very
'upgradable' and there are other choices in used equipment
that would be 'better' (FWIW).

Jim,
The quick and dirty answer is , yes. Folding part of the
folded dipole, or any other kind of dipole, back on it's self
isn't good, and has detrimental affects on the received signal.
'Doc

Exactly. So, apparently if the radiation pattern is the same, the only real advantage to it is the decreased size of the antenna.

The article's in the July 2001 issue of MT if you want to see what the details of the project are.

Thanks for the info...

Charlie,

I deleted your review because the manufacturer told me that they had never sold an antenna to anyone with your name or callsign.
Since there was no way to contact you (you have no email listed on eham), there was no way to confirm or deny the validity of your review. If you will provide me with information about when you purchased these antennas and under what name, I will contact Mel and confirm it. Then I'll put your review back up. I has not been deleted, I was just waiting for someone sane to send me mail asking why it wasn't there any more.

eHam has in the past had false reviews posted by competitor's products. In these cases,
I contact the person who submitted the review (if possible) to find out if it
is a valid review or not. We do not remove reviews for advertisers or anyone
else if they are valid reviews. The same will be true for yours.

I do not believe this is true. I would like you to produce an e-mail where anyone from our site gave you such information. If you can't, I would appreciate you retracting your statements below. I would also like to know under what callsign you submitted this alleged review so I can search the database for it. There is no mechanism to delete reviews, and I'm sure I will be able to either substantiate your claim or deny it.

Hmmmmm. Very interesting information.

"Charles Swartz" publishes a review under the call W3HRH, but that
call is listed to David MacLeod.

Stranger yet, the manufacturer says nothing ever bought under either
name!

I'm sure "Charles" can clear that all up. There must be a reasonable
explaination.

3814. Snap-on Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-12 03:38:47 UTC
From: Michael Carter <mikec@aviate.org>
Message-ID: <3C16D146.D9E89729@aviate.org>
Source record: 152967

Howdee. Question for those who know...

I have a 10m dipole I'd like to add a 20m segment to, effective making
it a fan dipole I suppose.

Anyway, I'd only be operating 20m sometimes, and have a limited space,
so I decided what I'd like to do is make the 20m segment "detachable".
I'd do this by using snap hooks to attach the 20m wire to the eyehooks
on the 1:1 balun, and alligator clips to clip the antenna wire to the
"tabs" there the 10m segment is soldered to.

Does this sound feasible?

thanks!

Greetings,

I'm in a temporary home for the next couple of years. I have a Cushcraft R-7 on a push-up pole that works reasonably well. I'm considering the T-25 so I'll have 160-10 meter coverage.

Anyone have any real-world experience with this antenna?

That particular movie, of 1951 vintage I believe, plays on the classic cable channels here every Christmas season, and it's one of my favorites. Another great Christmas movie is "A Christmas Story," an American movie shot in Canada, with Jean Shepherd narrating a story about a boy getting a b-b gun for Christmas, that movie plays here in the States hundreds of times every Christmas season. Hopefully y'all get it over in merry England, too.

Merry Xmas and a fat goose to everyone this year...

Hi Tom,

I modeled this antenna, and also understand how it "works". Not only hat but a Ham in this area had one, and it was very very poor on 160 and 80 meters.

It models to have very very poor efficiency on 160 meters, less than a small mobile whip, but in fairness it gets better as you go up in frequency. It is never really what I would say is good, but is acceptable on bands where it is longer than 1/4 wl.

You'll make contacts with it, but you would do much better with a Butternut or some other vertical if you could even install a marginal ground system.

I didn't catch that Bob, but you are right. He calls himself Charlie,
the e-mail address says Fred, he posted the "review" to E-ham under
the call W3HRH, and that call is registered to David A Mac Leod.

In spite of an obvious troll, he caught some fish who swallowed the
bait.

I wonder who it *really* is. Maybe someone who sells a similar
product?

E-Ham did the right thing, pulling the review. The guy is obviously a
fake.

I have an old hewlett-packard bolometer that seems to be in very good condition.

Can it be used to fine tune a 'C' band TVRO antenna?

Thanks
Spencer

3821. Re: Experience with Texas Towers (vs. Ham Radio Outlet)

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-12 05:09:46 UTC
From: "George, W5YR" <w5yr@att.net>
Message-ID: <3C16E697.C2ECA10E@att.net>
Source record: 152874

Well, maybe a lot depends upon how *you* conduct your visit and what your expectations are.

I have been visiting and doing business with Texas Towers since before 1982 and have carried something like 20 radios out the door, several antennas, and uncounted small items, many of which were not necessarily inexpensive.

Yet, when I go in the store, unless I greet Gerald or Matthew, or one of the ever-changing counter guys, they may or may not acknowledge my presence if they happen to be busy on the phone or with a customer. Rather, they continue to tend to their business and don't bother me as I look around the store. I greatly prefer this to the opposite situation wherein some fellow with maybe 1/10-th the experience I have in ham radio hangs on my neck pushing this and pushing that, etc.

On the other hand, I have never failed to receive a friendly greeting from Gerald or Matthew and a few minutes chit-chat if I greet them, ask a question, or whatever.

The point of all this is simply that TT is primarily a telephone-oriented mail order business. They maintain a small stock on display, but the real action is in the warehouse out back. They do not cater to the retail walk-in trade as do Fry's or Radio Shack.

Their role as a relatively small discount dealer is NOT to serve as a welcoming committee to new hams in the area. Their role is to provide a wide variety of quality equipment at reasonably competitive prices. While they are widely experienced and highly qualified and willing to discuss the technical aspects of their equipment by the hour, they are not in business, in my view, to deal with the new ham who walks in the door and says in effect "Here I am, educate me and convince me what I should buy since I know virtually nothing about amateur radio equipment."

If some folks find this posture to be cold and unfriendly, well, maybe they will just have to look elsewhere for the glad-handing treatment. Personally, I have never been in the store when I did not enjoy my visit and felt that I had been treated "right.".

I have related my perception and experience with TT. If Gerald and Matthew find that I have improperly characterized them, and/or TT, then I apologize. They remain my first, and frequently my only choice, as a source for amateur radio equipment.

I'd rather be 'passively ignored' when I'm just looking around than
get either of the treatments I tend to get at other stores; actively
ignored, where they actually hide when they see someone with a
question, or pursued like a supermodel in a trailer park.

Give them a minute to finish up the phone call they're on, and you can
have all your questions answered...and unlike most retail businesses,
the answers are highly likely to be right.

Hi Spencer,

Is it part of a waveguide mount? Or an N connector with cannister style fixture? Usually they are good to at least 12 GHz if not 18-24 GHz. Plumbing will obviously limit application (unless you have flange clamps and adapters).

Another matter, are you speaking of the meter movement, the load, or the two (meter + load)?

Finally, you wouldn't normally use a bolometer to tune an antenna, you would use a SWR meter. This would normally involve a crystal detector, slotted section with adjustable probe, and 1 KHz tunable AC meter (scaled in SWR and dB scales). Your source will also have to be 1 KHz modulated (AM/Pulse).

Be careful to not exceed the power limitation for the bolometer, some use a 1/20A glass fuse (I think, or similar low ampere fuse). If your source exceeds 10mW (unlikely for a generator, but a distinct possibility from "power" devices); then you should also be using a directional coupler (-3dB, -10dB, -20dB... depending on the extent of power applied to the load).

A folded dipole for 40M is still about 66' long. It is not shorter. The main advantage to a FD is wider transmitting bandwidth.

Regarding dipoles and other wire antennas, is there a rule of thumb or computation for dimensioning the separation of the two wires at the center insulator? Is there a "that's too close" threshold, or a "that's not close enough" threshold for how far apart you separate your center?

Should work. Might need strain reliefs to keep any pressure off the clips,
keep them from slipping...

Hi OM,

If they are too wide apart, the split feed makes up the difference.

In regard to the dimensions of most coax feeds, it's hard to imagine
them being too close togther.

> went in there to browse and when I've actuaaly bought stuff...

I've never bought anything from TT, but I was on an "antenna party" a
while back, erecting a tower for a friend. The model he bought
telescopes inside itself 3 times, which makes the top section rather
small. They recommend a Yaesu rotor for this particular tower. Well,
we had the recommended rotor and it wouldn't fit inside the
trianglular top section. (Yaesu has made a change to their rotor,
which makes it larger.) We called the tower folks and explained the
problem. They couldn't understand why we couldn't get the rotor in
there, so one of the guys at the tower company actually went outside
and climbed up on their tower and looked at the situation. (Their
older rotor fit in there fine, but the new Yaesu rotors will not.)
There wasn't much they could do to help the problem. Our friend
had already bought this tower and had spent several hundred dollars
getting it delivered. We ended up inprovising a way to use the tower
and the rotor, but it is a terrible way to have to do a new
installation. The antenna must be aligned perfectly to 274 degrees
before lowering the tower, or it will scrape the wiring off the side
of the rotor! If you're considering a new tower, make sure somebody
makes a rotor that will fit into it before it's delivered to your
door!
Always a new experience... 73, JJ

Well, theoretically they can be too close if they arc over at whatever
power level you are running. As a guess, I would say to look at the
conductor spacing of your feedline.

Lots of people use egg insulators. That makes the wires overlap in
3D space and it works fine. Whatever "not close enough" separation
you choose will be neutralized by the two wires in the transmission
line. In other words, if you put the two dipole elements three feet
apart, then three feet of the transmission line becomes part of the
dipole antenna. The actual electrical separation is the distance
between the two conductors in the transmission line.

Tom,

I figured there would be heavy losses on 160 and 80 meters. The antenna reminds me of a vertical version of the B&W TFD.

Since I've moved the tower and yagis are in storage (I do miss them...smile). I may just stick with the R-7 and limit my operating to 40-10 meters for the time being.

I'm not sure that Jason understood that a pair of wires in parallel a short distance apart approximates a single conductor of that width at RF, and four in a cage approximates a single larger diameter conductor. The effect is what makes a folded dipole a broader banded antenna. Maybe he understands now. Steve, maybe you could offer some specifics about this effect? I'm not where I can get to the books or I'd look it up. I don't recall how closely this effect parallels a single large diameter conductor, but it is close enough.
.

Message-ID: <3c179a74_3@news1.prserv.net>
Source record: 152889

Curious as to what is a "current type" balun, and how does it differ from any other type?

Also, in what cases are a 1:1 and 4:1 balun used?
What other common ratios exist?

I've seen plans for making baluns by looping feedline, or by stacking ferrite beads on a feedline.

Is there a good source of information on baluns and the reason they exist and are used?

David KB5YLG

So I think I'm reading...at least as wide as the dielectric radius, and after that, it doesn't really matter, because where the feed line separates from the dielectric, it becomes part of the antenna anyway.

Hi David,

You got it.

The only designs I've seen that are critical to spacing elements at
the feed point are for extremely wideband designs like a discone.

Source record: 152897

A "current" balun attempts to cause the currents in the two feedline conductors to be equal and opposite, which eliminates feedline radiation. The term was coined to distinguish them from "voltage" baluns, which cause the voltages on the two conductors to be equal and opposite relative to the "cold" side of the balun input. If an antenna isn't symmetrical with respect to ground, a "voltage" balun will unbalance the feedline conductor currents, causing feedline radiation. "Voltage" baluns are useful in some electronics applications, such as driving push-pull amplifiers; "current" baluns are what should be used for antennas. You can find more information in "Baluns: What They Do and How They Do It", in the ARRL Compendium, Vol. 1.

Source record: 152898

Hello -

I am new to this and enjoy everyone's insights on this group.

I recently installed a TV antenna w/rotor. From what I can tell, I must ground...
1. The mast itself
2. The coax
3. The 3-wire antenna rotor cable.
I understand 1 & 2, but am fuzzy on 3. Also, one of the rotor cable's wires is ground, but the control box has the 2-prong plug (one prong larger) which plugs into the outlet. Is that strange?

Are my two questions related?

Thanks in advance.

hey mike
i think as long as the mast you have the rotor mounted on is grounded IE stuck in the ground and grounded to another ground rod near by the rest of the things you asked about ground themselves the rotor grounds to the mast the coax ground to the mast when attached to the antenna the rotor cable is grounded at the rotor cause its attached to the mast so everything will be fine

Mike,
The whole idea for grounding is to keep any potential
lightning
strike from following the coax, or rotor cable into the 'shack'
and
into your equipment. If you can provide lightning 'easier' path
to
ground at a ground point outside the house, rather than following
coax or cables you've accomplished what you set out to do.
Sometimes
that means grounding or isolating rotor cables. Another easy
method
is disconnect the cables (just like the coax, etc.) at some
point out-
side the house. What ever is easiest and most 'do-able' for you.
'Doc

Source record: 152905

Theoretically, the actual distance between the extreme ends of the
dipole wires should be whatever length the dipole is supposed to be.
The short length of the wires connecting the inside ends of the
antenna wires to the feedline can be considered to be a part of the
antenna. But there's no need to worry till the feedline wires are
spaced apart by 2 or 3 feet on the 160m band - or 2 or 3 inches on
the 10m band - which is not very likely.

Only one rule of thumb is needed - "Don't drink and drive this
Christmas or your life expectancy will be shorter than an Afghan's."

Since the common mode choke makes the transition between a balanced
load (something you are missing) and an unbalanced line (something
that happens when your mirror tips), why is it not a balun?

I have a complaint about almost all RS salespeople in my area (Hampton, VA). That is all they are - salespeople, not electronics folk. And poor ones, too - don't know the product, don't even know the product is in the store, selling something 'new' in a box that is missing an antenna and has two of four batteries in it. And always trying to get you to buy something else, no matter that you came in for a $2 earpiece, they ask if you need a metal detector or computer or some other $300+ piece of gear - I prefer to spend my money, I don't want them trying to spend it for me, ya know?

I assume you are aware baluns are used to connect balanced (against ground) to unbalanced (against ground) transmission lines and circuits.

A "current-type" balun is often known as a "choke" balun. It is formed by winding a transmission line, coax or twin-line, around a ferrite rod or round a ferrite ring. Or by sliding a number of cylindrical ferrite sleeves (slugs or beads) over a short length of coax line. Although often described as 1-to-1 they are NOT impedance transformers.

The end result is the same - the two wires of the line together behave as an RF choke and present a high impedance to currents flowing along the feedline, the two wires behaving as one wire. The only effect on normal feedline operation is to increase the length of the line by the actual length of the line wound on the ferrite core, only one or two feet. Ideally, the length of line on the balun is too small to have any effect on the impedance-transformation ratio of the line as a whole. It is just a very short length of line without any impedance transforming properties. It has a small phase shift proportional to its short length, the ferrite having no effect. Input impedance is sensibly the same as terminating impedance. The length of line wound on the device should be appreciably less than 1/4-wavelength. They can be used as baluns, un-uns or bal-bals

4-to-1 baluns are 4-to-1 impedance auto-transformers also wound on ferrite cores. The two (equal-number turns) windings are connected in series in a special manner to improve the HF response. Inter-winding capacitance and leakage inductance then have a much smaller effect. But the 2-to-1 turns ratio predominates - the input and and output voltage ratio is fixed at 2-to-1. Depending on connections they can be used either as a balun or a un-un. But never as a bal-bal.

>...the common mode choke makes the transition between a balanced load...<

Not to flush your definition, but one may use a commode choke anywhere along any conductor (I have one installed where the feed from my 75-meter dipole enters my shack). True, it functions AS a balun when installed at the transition between balanced and unbalanced lines or loads, but can't you use it elsewhere? Like on a phone line, radiating computer line, a guy wire, or a mid-boom coax drop from a vertically-mounted long-boom Yagi? Heck, commode chokes get rid of all kinds of ....stuff, don't they?

I just got the January 2002 of World Radio today. On page 20 there is an article about a 21 foot 75M vertical. It's constructed with 4" PVC. The construction details are not real clear, but the material list calls for two rolls of 2" copper tape and a homebrew loading coil. From what I see, the 2" copper tape is applied to each side of the upper and lower sections of PVC with the trap in the middle, hence making a 4" diameter element!
FWIW, World Radio is at www.wr6wr.com . As of today, the article is NOT posted on the Web, but I guess you can probably get the magazine from the site if you are interested....

As a public service to the NG, I will be offering to sell mobil amps to those wishing to buy them. This is not done out of greed but out of necessity to thwart the losers in the NG who think they have taken over OUR nice little group and can use it to harass and belittle as they see fit. To offer sale of these items is just the thing needed in a public forum to mess with these nil-minded simpletons.

Amps such as Texas Star, Palomar, Cobra,Messenger, Gray, Galaxy, X-Force and so on. These will be sold for a limited time and at a VERY small profit IF ANY !

This is not a money thing so much as it is an access thing.

Since these self appointed radio/computer gods have declared knowledge an illegal thing also, I might just make the entire Secret CB book series available on CD along with a CD of amplifier schematics for base and mobil amps. Why is it that when these morons just think they are getting somewhere in their fight somebody like me comes along and pisses on their parade? BECAUSE THEY NEED IT AND DESERVE IT!!!!!!!!!

E-Mail me with your needs......

The turnstiles and fan dipoles I like are using a "fat" element on one
sense. The fan dipoles probably more than the turnstile, although I
think the turnstile would qualify although the elements are at right
angles. Maybe that has something to do with why I seem to have
slightly better performance on 75m with those over a standard dipole.
I converted my antenna back to a turnstile on 80m yesterday. I want to
do some tests with it. BTW, They were supposed to have a spark gap
transmitter running on the low end of 80m last night. I wanted to
listen for it, but I was tired and passed out about 45 min before it
was supposed to go on. Dang...I wanted to hear it. Never have heard
one running before...MK

What can you say when you pay the help at minimum wage and/or on a
commission bases? You get a work force of minimum knowledge and skill.
That is what the bargain shopping public demands, everytime they part with a
dollar to pay for the cheapest priced item/service. This doesn't *just*
happen at RS but all over, in every business/goverment agency and so forth.
If RS service is so bad and disturbing to the shopper, then they should stop
shopping/purchasing (voting with the wallet) there and take their business
somewhere else. Problem is, there is no place else. This tells you there
is just a small market nitch in the everyday electronic home gadget builder
catagory. Selling the nickel/dime items will not pay the bills, so the
bigger ticket items must be pushed if there is a hope of staying in business
for tomorrow. So, get use to it.

3864. Looking for recommendations on 6m beam

Frankly, I don't see anything wrong with the Cushcraft antennas. I have a 5-element 6-meter which performs very well, and we have some high winds here in north/central Arizona. If I wanted to go for the gusto, I guess I would go for something like the Force 12 EF-906 on a 30' boom. They run about $550. Note that Force 12 will custom fabricate an antenna for you. I'm sure they would be glad to come up with exactly what you want if you are willing to spring for the BIG bucks. They build antennas that will survive 100 mph winds, so that should give you that "industrial strength" you are looking for.

hey neil
i would suggest the M2 6M5X its a 5 ele yagi on a 15 foot or 18 foot boom i dont remember but its an excellent performer but any of the M2 antennas would do you very well you can buy them direct from M2 or usually get a better deal going thru a retailer like SSB or texas towers

good luck oh and you may want to do a good grade of coax usually poor perfprmance can come from that too and just make you think the antenna is junk...grin

What you propose should work just fine. However, you don't have to make
it detachable.

Being that you have limited space, one option might be to make your dipole
into a trap dipole by adding a trap at the end of the 10 Meters elements and
then some extra wire to get the antenna to load properly on 20 Meters.

A trap will automatically isolate the 20 M section of wire when you are
operating on 10 Meters. On 20 Meters the trap will act as a loading coil
and shorten the length needed to operate on 20 Meters. I have a trap
dipole that is built for 40, 20, 15, and 10 Meters and it works great.

You can do a web search and come up with lots of information on trap
dipoles. If you don't have a grid dip meter, have a friend who does
check the trap for resonance before installing it on the antenna.

Message-ID: <9387eabc.0112130953.3ea1532f@posting.google.com>
Source record: 152918

I'm thinking of adding a Comet SBB-1 antenna to my collection. I also have a Comet Z780 that I think is fantastic. I would like an antenna that isn't 'hanging out there' quite as much as the Z-780 for long road trips.

I'll be using both for marshalling SCCA ProRallies, and will probably switch from the SBB-1 to the Z-780 once I arrive at my marshalling station.

Does anyone have any ecperience with the SBB-1? Likes? Dislikes?

TIA for the input!

JB

i have used the m2 6m5x for about 18 months and it works like a fire host.
well built, low swr,
excellent gain, good pattern. highly recommended

3873. Re: WHAT IS "CURRENT TYPE" BALUN?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-13 18:38:06 UTC
From: Richard Clark <kb7qhc@attbi.com>
Message-ID: <0pqh1ucagu9qlppcajmja1rbcs32kgvvrg@4ax.com>
Source record: 152826

On Thu, 13 Dec 2001 17:41:06 GMT, "CW" <clinton.magers@attbi.com>
wrote:

>Pick a point, Richard. Some of us (I) want to hear it.

Hi OM,

point in fact:
>4-to-1 baluns are 4-to-1 impedance auto-transformers
is the usual flaccid description of BalUns that lead others to think
of them in terms of the standard magnetic field coupled power
transformers with 5000 windings around an iron core the size of a
volkswagen. This old wive's tale then perpetuates into issues of
"core saturation."

Then we have the creation of an issue from whole cloth:
>The length of line wound on the device should be appreciably less
>than 1/4-wavelength.
Which of course abnegates a class of BalUn that is line length based
and very much this size. And to what end? The standard HF BalUn
would have to be operated in the UHF for this to even approach the
possibility of being "this" specific problem. Reminds me of a British
sit-com where another old lady continually admonishes her husband's
driving:
"Watch out for that cyclist dear!"
(husband whips his gaze around in confusion and sputters)
"That cyclist is on the other road going the other way!!!"
(old lady sits back smugly)
"We wouldn't want to be late with an accident would we, dear?"
["keeping up appearances" I think it was called]

And of course there is the last but not least, a classic howler:
>Depending on connections they can
>be used either as a balun or a un-un. But never as a bal-bal.
As if the device could tell, and magically change its characteristics
(sort of a technical "class distinction" which leads my thoughts back
to that sit-com again).

Oh and buried in the same paragraph, our old lady's waltz lights up
with:
> 2-to-1 turns ratio predominates
with the merry air of spinning yet another tale of "turns ratio" (a
magnetic field coupling term mis-applied as I forecast above).

Reminds me of the admonition: How much would you trust an airline's
commitment to safety when they can't fix the food tray in front of

you?

darn it........I have newsranger blocked and missed this post so I'll
address it now...........Eat shit and die! Who sells what or who's buying is
of no concern to you.......You just need a reason to cry like the little
child you are. Grow up! Your little click isn't going to even put a dent in
what gets sold for CB radio legal or otherwise.
Being in radio as long as I have and knowing the people I know........It's
going to be a long long time before slime like you will ever be able to do a
damned thing to anyone selling radio stuff. I have more radio info on CD's
and a larger database than most of you clowns would ever dream of and if
need be ALL WILL BE PUT ON A WEBSITE. Everything from schematics for amps
that we were building in the 70's and 80's to every last page of master
editions.....secret cb.....green, gray, black books.........You name it and
I got it. Nothing you sleazy little shits can do will EVER stop people from
getting information they need. Bet on it!

Subject: MOBIL AMP SALE
Date: Sat, 14 Apr 2001 19:09:40 GMT
From: "Train" <cbmods@optonline.net>
Newsgroups: rec.radio.cb

As a public service to the NG, I will be offering to sell mobil amps to those wishing to buy them. This is not done out of greed but out of necessity to thwart the losers in the NG who think they have taken over OUR nice little group and can use it to harass and belittle as they see fit. To offer sale of these items is just the thing needed in a public forum to mess with these nil-minded simpletons. Amps such as Texas Star, Palomar, Cobra, Messenger, Gray, Galaxy, X-Force and so on. These will be sold for a limited time and at a VERY small profit IF ANY !

This is not a money thing so much as it is an access thing.

Since these self appointed radio/computer gods have declared knowledge an illegal thing also, I might just make the entire Secret CB book series available on CD along with a CD of amplifier schematics for base and mobil amps. Why is it that when these morons just think they are getting somewhere in their fight somebody like me comes along and pisses on their parade? BECAUSE THEY NEED IT AND DESERVE IT!!!!!!!!!

E-Mail me with your needs......

Happy Holidays all. I am working on a Cushman CE-4 and need to know if anyone might have a manual that can email or snailmail me a copy of one or two pages. I have found out that there is a problem with a board on the bottom of the unit. The 0710-7001 board had two transistors that went up in smoke. I cannot find my manual for this model and the CE-6 seems to have different boards.
It is the fourth board on the bottom front row, counting from the bottom

as the unit is on the bench facing you. It has three pots and a horizontal potted coil, and two IC's on it. There are a bunch of transistors located near the edge connector, toward the right side of the board. I need to know the numbers of the transistors and some of the values of the parts. Thanks Don KB6GQA

3877. DX-Central betrays it's $$$ contributors

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-13 20:38:58 UTC
From: Charles Johnston <ctj92@cableone.net>
Message-ID: <3c1911f0$1@news.bnb-lp.com>
Source record: 152831
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment

After they ask and receive who knows how much $$$ through voluntary
contributions they now switch software to some one-of-a-kind
never-before-heard-of "WinCluster Lite" node software.

Nearly _all_ the user-side cluster commands are no longer available
such as custom login commands and filters. That's right ..no user-side
filters. In fact there are only 10 user commands available. With either
CLX or AR cluster software there are 2+ printed pages of user commands.

The reason as explained to me (by the software author) is that
contests put such a load on the software it wasn't able to keep up.
Well duh....I thought all this time I was contributing to a DX cluster
and not a CONTEST cluster. There are DX spots going on every
day...contests are only once-in-a-while.

Is it me or is this a case of the tail wagging the dog? Are they
transforming a DX cluster service into a CONTEST cluster service without
regard for DX'ers? Maybe they are contesters themselves and "to hell
with the DX'ers"

Then I was told (after being one of the first to contribute $$$) that
since I left the cluster I am now a 'taker' and not a 'giver'. I have
informed them I want my money back..I suggest others may want to make
the same demands. This will give us all a chance to see their true
colors...

I was told (before contributing $$$) I would be helping to improve and
support a DX cluster..not some CONTEST cluster with half-baked
software....

So..if you are missing user features you have come to expect through the
years then you better look elsewhere.....DX-Central ain't the same
anymore.....

Well, if anyone cares, I have been using the array now for a week and it really works.
Have a dipole on 15 m height to compare with.
Amazing to watch the signals coming up from the noise when going from the dipole to the Bruce.
Feeding with 450 Ohm ladder line in the middle of one vertical element.

I have 2 trees about 100 feet apart with my house centered between them. It looks like a great opportunity to hang a dipole. I've fought with EZNEC for about a week trying to model a multiband dipole for 20, 17, 15, 12 and 10 m. It seems that no matter what I try I still end up with sky high SWR on several of the bands.

Anyone got any secrets that'll help me get all the wire in the air, and all the signal through it?

Thanks!

Hello Dave,
W9INN Antennas manufactures a full line of wire antennas including
some multi-band dipoles.

One of his more popular ones is the MPD5-78' or 87' 5-band
(10-15-20-40-80m) that has resonance on each band and is rated for 1500w
pep.

His web page is on the web site listed below. There are
illustrations,measured data and contact info.
Check it out....

Use rotor cable with at least 5 conductors. Cut each conductor for
resonance on the desired band (468/f where f is the freq in mhz of the band
center). Hang from tree using rope, pulley with counterweight is nice but
may not be needed depending on how large the trees are. Feed with coax.
Trim to final length using swr or antenna bridge. Cheep, easy to replace or
add more bands. remember experimenting is half the fun. 73 Ed KC4FD

Source record: 152838

I've found this to be a lot trickier and time consuming than it seems from this posting. Maybe it's just me. The lengths for all but the longest wire end up being quite a way from 468/f. There's a lot of interaction, and you've got to do the longest wire first. When you're done, the antenna will be narrowbanded. I guess it can be made to work, but when I tried it I ran out of patience before I got the antenna I wanted. Experimenting is fun, but it has its limits. . .

What bands does your rotator-cable antenna work on? Can you cover the whole bands with a reasonable SWR?

Mike,
I'm afraid I'm not going to be much use to you about the 'isolating' of rotor cables. I do know that one of the commercial 'ground' places has a device to provide isolation for rotor cables, but I just don't rememebr the name of the company. I do rememebr it isn't cheap.
The simplest method of disconnecting the cable outside, is to find a male and female connector with the proper number of conductors. Splice it in-line, and just plug, and un-plug as needed. I'm sure you could figure that one out, so I guess I'm really not any help... Sorry.

I know it is convenient to not have to retune when changing bands.

But if I could ge both ends of my dipole up 100 ft, and about 108 feet long, feed it with ladder line and a tuner, I would have super operation on 160 to 6 meters. The tuner has to be a good wide range tuner, not just a band flattener like so many internal tuners. I write down the settings and can switch bands quickly. I think that one band is difficult to feed with this setup. If you can, vary the length a bit so you do not miss that band, you win. I have not tried it but a single dipole in parallel

I have best luck with a 1 to 1 balun made with a few turns of coax just outside the house at the bottom of the ladder line.

You do not want to use a W2DU or even a toroid balun for a wide band non resonant antenna. They work well for antennas that are already 50 or 200 ohms (i.e.. already matched to the balun design impedance)

This is sure better than a forest of wires at lower heights for DX.

Losses in the tuner and feed line are simply not a factor with this setup. And if you have a good ground, you can tie the feed line together and have an excellent top loaded vertical for the low bands.

Aloha,
John KH7T

>can get to the books or I'd look it up. I don't recall how closely this effect
>parallels a single large diameter conductor, but it is close enough.
>.
>Dick
>

Hi Dick,

Well, I'm not Steve, but I think I know the answer. There is an equation in an old edition of Jasik's Antenna Engineering Handbook, 1961, First Edition, on Page 21-16 for cage dipoles:

"...For a multiwire cage type dipole, the effective cylinder radius (aeff) may be determined approximately by:

aeff = a * (n * a0 / a)^(1/n)

where
a0=radius of each wire
n=number of wires
a=radius of cage..."

I also saw the article in World Radio and couldn't figure out where he put the copper tape. If I had to do it, I'd spiral the tape around the PVC mast. A wide thin conducting strip has much less ohmic loss at RF than #12 wire so it's a good idea anyway. Hmmm...now where's the equation for that one.....

You can get aluminum tape more easily than copper and it's almost as good. It's used in HVAC duct work.

Hello Zulu Warrior...
I think you mean "resonactor". That term was coined by W9INN (Bill) to describe the trap-like devices used on some of his antennas. The great feature about them is that they have no physical capacitor component in them. Therefore the "resonactors" are very stable in in all environments and are rated at 1500w pep.
There is a capacitance in the "resonactors" as a result of the spacing of the wound wire on the core forms.

HTH

Hi Dave,

You can try to optimize the feedline and flat top lengths to obtain resonances at all of your desired frequencies, like a G5RV does. My calculations show that you should use a 123 foot flat top and 89 feet of 300 ohm twin lead to obtain resonances at 14.0, 18.07, 21.0., 24.9 and 28.0MHz. The problem is that the patterns on such a long wire at these frequencies have many lobes, over half of which are at high take off angles which are useless. This is because the closeness of the frequencies requires impedances to change rapidly with frequency to get around to the next resonance. There is some info at the web page below on how these lengths were arrived at.

The best answer is probably a log-periodic if you have the room.

I use a 33ft rotatable dipole for 20m-10m. I feed it with 300 ohm ladder-line and I don't use a tuner. SWR is less than 1.5:1 on all bands between 20m and 10m because I feed the system at a current maximum point. The theory is covered on my web page for an all-band HF antenna.

Model a 33ft dipole with the transmission line. Change the length of the transmission line for lowest SWR. It's a piece of cake.

Ed, have you ever actually built, installed and tuned up an antenna just
like you described?

If so, how on earth did you tune it? I don't mean with what instruments but
with what procedure? How did you lengthen those wires which turned out too
short when cut to "formula length"? How did you deal with those wires
within the flat cable that had to be shortened? How many iterations did it
take to get a usable SWR on all bands?

It boggles the mind . . .

I am curious about that statement, John. I use three W2DU baluns to transition ladder line to coax into the shack and none of them show any indication of being frequency sensitive from 80 through 10. One of the defined advantages of the W2DU bead balun is its lack of frequency sensitivity and its ability to be virtually insensitive to differential-mode SWR on the line.

I need some words of wisdom here . . .

They asked for contributions for the upgrade of equipment at DX-Central. I gladly gave what I could with the understanding the DX Cluster would be upgraded. Apparently they had enough funds to buy new hardware (and they are still begging for $$$) but they did away with the existing full-featured software (CLX).

The explanation I got was that now (after the hardware upgrade I helped pay for) their software (CLX) was all of a sudden no good. So they removed a full featured cluster software package and substituted a software product that does not have near the number of user-side custom settings like filters,automatic login scripts, being able to block spots originating outside of USA etc...the list goes on....it is best described as some kind of beginner and / or basic cluster software...a stripped down gutted-out cluster software package....it is also a one-of-a-kind...no other DX cluster on the planet uses it. Why would they? It has basically no usable features compared to what has already been available for years!

This "upgraded" software (WinCluster Lite) is a very bare bones application that does not even begin to retain the level of performance we have all grown accustomed to over the years. They ask for contributions to improve the service and what we got was a HUGE downgrade in the software to the point it is unusable for anyone serious about DX'ing....

Bottom line.....
What I got and everyone else got for their $$$ is a crippled hardly usable dx cluster. It is a gigantic step backwards....it has in reality REMOVED many.many vital services and features.....WinCluster Lite is a joke for serious DX'ers....trying to work DX with it as a service is ridiculous....

I live in a very wet environment, especially during winter (Seattle). I am putting up a tuned feeder doublet at my house, and I wonder if I coat the ladderline with silicone, perhaps Armor-All or some such product, will that help to *reduce* the detuning, hi-SWR effects of water on the outside of the line? It should make the line shed water more quickly than without, so I am thinking that will be a big help.

Hi Will,

The lines can be dripping wet with no problem - until the water sheds
across the distance between them on an "insulator."

Ladderline here in Seattle is a losing proposition. Any perceived
bounty of 1:1 matches may in fact be going to boiling water for tea
(uh, coffee).

Hi David,
perhaps the no-tuner all-band antenna by W5DXP might do. The original
is designed for all bands except top-band and is 130 ft long. You
would have either to bend the ends somewhere or change the
configuration a bit. See http://www.qsl.net/w5dxp/notuner.htm for more
info.

> within the flat cable that had to be shortened? How many iterations did it
> take to get a usable SWR on all bands?

I started out with F/468 and added a couple of percent.
I made a setup with pulleys so that I could bring the antenna
up and down fast. The rest was simple math and the MFJ-259.
Being conservative in my trimming (focusing on longest first),
it took about a half an hour, but that 75 foot roll of four
conductor rotor cable became a nifty 10/15/20/40 antenna
with less that 1.5:1 on all bands.

I later did the same thing with some five conductor cable on
the SWL bands, and it was a vast improvement over the
dumb long wire. Not bad for five bucks.

Message-ID: <0cgj1ug19uoknhar9s6t83a4vncc241ikt@4ax.com>
Source record: 152863

I am now accepting orders. Overseas shipment is confirmed. 20 3'
antenna and feeds to arrive in about 14 days. 3 taken.
I have worked very hard to bring these antennas into the country after
they were made to my design. These antenna are NOT BBQ grills posing
as microwave antenna. These are the real thing. I'm not a big
company, i'm just a Ham like you trying to fill a void out there. I
was amazed that there wasn't a single company making anything of real
quality for AO-40, so I thought I would give it a try. I hope I am not
offending anyone by posting here. I'm just trying to get the word out
and save possible customers the cost of advertising.

Drop by my new web site and look around. Leave me a comment if you
like.

Not so. There's a strong electric field between the conductors. Water is very lossy stuff at RF, and even isolated droplets on the dielectric between conductors result in considerable loss. Years ago I tested some good quality 300 ohm twinlead. When wet, the loss was greater than RG-58 when matched.

The only solutions to the problem I can think of are to use coax, as I do, or go to real open wire line with a minimal number of insulators. Oval TV twinlead would also probably be better if you can keep water out of the inside (and horrible if you can't). But maybe some kind of coating would help. I did find that the loss was greatest when it first rained, presumably because of accumulated dust. After the line had time to get washed by the rain, the loss was still high, but not as high as when it first got wet.

Will,
It may help for a limited time, but unfortunately, theres
really no 'cure' for wet ladder-line. I have no idea what the
dialectric properties of 'Armor-All' is, but the 'cure' may be
worse than the problem. It can't hurt, I guess, so give it a
try...

Dave,
Don't worry too much about modeling the antenna. Use the
'standard' "468" formula (with a few extra inches for a 'fudge'
factor, and trim for best SWR. All the modeling programs are
dealing with an 'isotropic' antenna, so the actual measurements
will be slightly 'off' (too long). It takes a little time, but
this kind of antenna is certainly 'do-able'...
'Doc

AMATEUR RADIO NEWSLINE(tm) REPORT #1269 - DEC 7, 2001

Amateur Radio Newsline report number 1269 with a release date of Friday, December 7, 2001 to follow in 5-4-3-2-1.

The following is a Q-S-T.

The FCC says no to a Winter Olympics special call sign and a new Extra class exam starts next summer. Learn what's in it on Amateur Radio Newsline report number 1269 coming your way right now.

(Billboard Cart Here)

**

THE 2002 WINTER OLYMPICS: FCC SAYS NO TO SPECIAL CALL SIGN

An idea for a special events call sign to celebrate the 2002 Winter Olympics has drawn a negative response from the FCC. Tom Schaefer, NY4I, of Sandy, Utah, had requested that the agency allow amateurs Utah hams to substitute the number 2002 or 02 for the 7 in their callsign. This, for the time period preceding and up to though the 2002 Winter Olympics in Salt Lake City. But after mulling it over for a few months the Schaefer says the agency responded with a definite no:

--
Schaefer Here:
In-Q: I wrote a letter...
Out-Q:...as a different prefix.

The letter to Schaefer was signed by D'wana R. Terry. Terry is Chief of the Public Safety and Private Wireless Division of the Wireless Telecommunications Bureau. Among the reasons Terry stated in refusing the special call sign request was that the block of special event callsigns requested did not fall into the commission's special event callsign format. Also, that the request was inconsistent with International Radio Regulations. Schaefer says that he is disappointed at the FCC decision to deny, and also a bit surprised:

--
Schaefer Here
In-Q: The letter I...
Out-Q:...unable to do that.

Does this mean that there will be no ham radio involvement in the 2002 Winter Olympic Games? Not by a long shot. According to Schaefer members of the local ARES groups will be assisting in providing communications for the event. And

there’s a good chance that someone will pick up the ball and get some sort of special call sign using the established call sign administrator program.

By the way, you can hear more with Tom Schaefer NY4I about ham radio at the Winter Olympics on this weeks RAIN Report. Its on the web in Real Audio and Windows Media at www.rainreport.com and by telephone at 847-827-7246. That’s 847-827-RAIN. (ARNewsline(tm))

**

THE ARCTIC WINTER GAMES

Another event called the Arctic Winter Games are also in their planning stages. In this case, ham radio is an important part of the event. Q-New Graham Kemp, VK4BB, tells us the who, the what and the where:

--
Greenland and the call-sign OX1AWG is on the air from Nuuk Greenland as a participant of the Arctic Winter Games going to be held in Iqaluit Nunavit and Nuuk Greenland 17th - 23rd of March 2002.

OX3HX, Rene tells us any Hams bringing a valid License original will be welcome to use the local club station OX3NUK for a small fee. If you would like to have your own OX3-call, ship a copy of the license but they need to have the papers 3 weeks in advance. Hams who like to operate OX/Home call or OX1AWG are welcome too, and have only to show up with original valid license.

For the Amateur Radio Newsline, Im Graham Kemp, VK4BB, of Q-News Australia.
--

For those planning to visit Greenland for the games, Rene Witkowsky, OX3HX will be available at one of the many Help Booths around the city. (Q-News)

**

DX RECORD: 73 KHZ DISTANCE RECORD INCREASED

Yet another new low frequency record has been achieved on the 73 kHz band. Jeramy Boot, G4NJH, has more:

--
“On the 21st of November, just before midnight UTC, W1TAG received extremely slow CW from G3AQC. This was the first time that a complete callsign had been copied, though partial calls were identified the previous night.

The opening lasted around two hours and was the culmination of several weeks of testing. At a distance of 5291 kilometers, G3AQC smashed his own record of 4408 kilometers when his 73kHz transmissions were received by VE1ZJ last June. He was running 200 milliwatts ERP.

The transmission was in Differential Frequency CW, where the dots and dashes are the same length but on slightly different frequencies, and with no space between them.

Jeramy Boot, G4NJH”
--

The Differential Frequency C-W communications system used for this contact holds the promise of extending this record even further. (GB2RS)

**

BREAK 1

This is ham radio news coming to you from the United States of America. We are the Amateur Radio Newsline, heard on great bulletin stations around the world this week honoring the Antelope Valley Amateur Radio Club Wednesday Night Net serving Lancaster California.

(5 sec pause here)

**

HAM RADIO IN SPACE: EXPEDITION 4 HEADS TO THE ISS

Amateur Radio is keeping an eye one space this week. On the International Space Station to be more exact, as we witness a changing if the guard. The third group of Astronauts and Cosmonauts headed by Frank Culbertson, is getting ready to come home. They’ll be back on Earth December 16th, after being in orbit since last August.

Expedition 4, Yuri Orufrienko, Dan Bursch and Carl Walz will take over and be up there until next May. Onufrienko once operated from the Mir Space Station; Bursch is KD5PNU and Walz is KC5TIE. So hams can look forward to contacts with them.

Amateur Radio on the International Space Station; ARISS; will continue on the air with two meter voice and packet. Voice contacts with schools all over the world have been well served and those exciting contacts will continue at a rate of one or two a week once the new crew settles in.

In addition to operating ham gear, the new crew has also carried new Amateur Radio antennas to the station. They were designed and built in Italy to Russian specifications, then space-qualified and shipped to the United States.

The Astronauts plan at least eight space walks, two of which will be used to install those antennas outside the crew quarters. They should provide a wide range of frequencies and vastly improved coverage of the ham bands for the ARISS station.

The space station call, while flying over the United States is NA1SS. The 2 meter downlink frequency is 145.80 MHz. Look for the new crew on the air from orbit in the near future. ARNewsline(tm))

**

HAM RADIO TESTING IN THE USA: NEW EXTRA CLASS EXAM QUESTION POOL RELEASED

If you are planning to upgrade to Extra class, now might be the time to do it. This is because a new and somewhat more difficult Extra Class exam will go into

effect next summer. Amateur Radio Newsline’s Norm Seeley, KI7UP, has the details:

--
The National Conference of Volunteer Examiner Coordinators Question Pool Committee has released a revised and expanded set of Element 4 Amateur Extra questions. Use of these questions begins next summer and replace the current Extra class question pool released back on April 15, 2000. That’s the day Amateur Radio ''restructuring'' became effective.

The new Element 4 pool expands the number of questions by more than 20 percent. The new test pool has 806 questions as opposed to 665 in the current Extra class pool. It also contains more technical material. In fact, more than half of the questions cover electrical principles, circuits, signals and emissions.

The 50 questions in an Extra class examination are drawn from the question pool. FCC rules say that an applicant must correctly answer at least 37 questions of the 50 to receive a passing grade.

The new Extra class question pool becomes effective July 1, 2002, and must be used to generate all Extra class written examinations administered on or after that date. The questions are available on the ARRL Web site and will remain valid through June 30, 2005.

For the Amateur Radio Newsline, I’m Norm Seeley, KI7UP.
--

The Question Pool Committee now will turn its attention to developing an outline for the Technician class Element 2 question pool. A draft version is scheduled for public release and
comment next spring. The ARRL website address is http://www.arrl.org/arrlvec/pools.html to find the Question Pool. (ARRL Bulletin, NCVEC)

**

HAM RADIO TESTING IN THE U-K: UPGRADING MORSE TESTS UNDERWAY

Meantime overseas, the United Kingdom is in the process of administering a lot of slow speed Morse code exams. This, following the an announcement by that nations telecommunications agency that U-K Full and Intermediate Class B license-holders can operate on the High Frequency bands under the new Foundation license by simply passing a code test.

Called a Morse Assessment exam, the Radio Society of Great Britain is arranging for sessions to be held nation-wide. The RSGB hopes that at least two sessions per region will take place between now and the end of December.

The RSGB says that these tests are open to both members and non-members of the society. So far twelve sites have been approved for training and testing of the new U-K Foundation License. (GB2RS)

**

ENFORCEMENT: AMATEUR RADIO ROAD RAGE MUST STOP

The FCC's chief ham radio rules enforcer has told those attending the Ft. Wayne Indiana Hamfest that the time for on the air arguments has come to an end. Riley Hollingsworth, the FCC's Special Counsel for Amateur Radio enforcement told the forum that Amateur Radio road rage must stop now and that the bickering on our frequencies can do nothing but hurt Amateur Radio in the long run.

Hollingsworth also says its time for more hams to get involved in public service. Jack Parker, W8ISH, of Amateur News Weekly, has that part of the story:

--
"Hollingsworth says that it is now time for hams to use frequencies responsibly. He adds that now, more than ever, is the best time for all Amateur Radio groups to seek out and establish working relationships with local emergency response agencies.

Since September 11th, Amateur Radio and its potential has moved into a prominent position on the national front. But he stresses that we must move quickly at a local level to establish our place in the overall emergency response plan.

Reporting from the Ft. Wayne Hamfest, for amateur News Weekly, I'm Jack Parker, W8ISH."
--

Hollingsworth's views are echoed by many who are already involved in organizing ham radio emergency communications on a local level. They say you can never have to many well trained volunteers. (Amateur News Weekly)

**

SPECTRUM USE: FCC OPENS UP MORE SPECTRUM TO COMMERCIAL USERS

The government has moved to eliminate a cap on how much spectrum any one wireless company can own in a given market. The decision opens the way for mergers between major carriers and allows them to provide more mobile services such as high-speed Internet access.

The Federal Communications Commission had previously limited the amount of spectrum that an operator could own in a particular geographic area, in an effort to prevent a single giant company from squelching competition in that market. But in a recent 3 to 1 vote, the agency decided to immediately raise the amount of bandspace a company can own from 45 MHz to 55 MHz. This is an increase of more than 20 percent. The FCC plans to completely eliminate the limit in January 2003. (FCC)

**

HAMVENTION 2002: TIME TO NOMINATE REMINDER

Another reminder that the Dayton Amateur Radio Association has opened the nominating period for the 2002 Dayton Hamvention Awards. There are three

awards presented each year. They are the Radio Amateur of the Year, Special Achievement, and Technical Excellence.

All amateurs Novice through Extra are eligible. Awards are decided by the Awards Committee, based partially upon the information received. Magazine articles, newsletters, newspaper clippings, videos and the like are appreciated but cannot be returned. The deadline for nominations is January 31, 2002. Nominations can be submitted by US Mail to Post Office Box 964, Dayton Ohio 45401 or by completing the convenient e-form on the web at www.hamvention.org. (DARA)

**

NEW HAM TECHNOLOGY: THE ELECRAFT RIG CONCEPT DESIGN CONTEST

Want to design the ham rig of the future and maybe win a prize? Well, Elecraft says that it will be giving three of its new EC1 project enclosures to those who submit the most interesting suggested designs concepts.
--
Eric Swartz WA6HQQ: “There’s quite a strong building and homebrewing community inside of the QRP’ers -- the low power operators -- these days. In fact, that is how we got our start.

We have broadened our audience past that and have pulled a lot of hams from the mainstream higher power groups to it also, but those guys (the QRP operators - ed.) build an awful lot of stuff. We are continually seeing folks talking about new project ideas and new things to design. It is quite a fertile group of people so I think we are just kind of servicing that need.”
--

Elecraft says its taking this rather unusual step to away to help stimulate the creative process within the ham radio community. According to Elecraft’s Wayne Burdick, N6KR and Eric Swartz, WA6HHQ, design concepts submitted can be for virtually any ham-related application, but they must be compatible with the Elecraft EC1 enclosure. The EC1 is the same size and color as the K1 transceiver. No schematics are required and designers are under no obligation or expectation to actually build the proposed projects. More information on this unique design contest along with all the rules is on the web at www.elecraft.com. (Elecraft)

**

ELECTRONIC BUSINESS: AILING POLOROID FILES CHAPTER 11

Polaroid has been known to generations of consumers for its instant cameras and film, and more recently as a supplier of digital imaging products. Now Poloroid has filed for Chapter 11 bankruptcy protection.

According to news reports, the company was unable to keep up with the new digital technologies of the photography world. It also has struggled with nearly $1 billion in debt. (Published reports)

**

BREAK 2

News never goes home for the holidays and neither do we. We are the amateur Radio Newsline with links to the world at our only official website - www.arnewsline.org.

**

EMERGING TECHNOLOGY: BRAIN DISEASE SUPERCOMPUTER

The University of California at San Diego will coordinate a consortium of interests banding together to build the first nationwide computer network for studying diseases of the brain. The network will enable researchers to share information on neurological diseases such as multiple sclerosis, schizophrenia, Alzheimer's disease and Parkinson's disease. The National Center for Research Resources, part of the National Institutes of Health, awarded the consortium more than $20 million for the project, which will enable researchers to share brain images via a high-speed network. (UCSD release)

**

HAM RADIO IN SPACE: FREE UPDATED TRACKING SOFTWARE

An updated version of the PREDICT satellite tracking and orbital prediction program is now available. This latest updated corrects some errors that have caused instability under certain conditions in the past. The program's documentation has also been updated, and new versions in Portable Document File and HTML have been added. PREDICT is free software.

The latest DOS version may be downloaded from ftp://ftp.amsat.org/amsat/software/PC/tracking/predict2.zip >. Further information on PREDICT software is available at http://www.qsl.net/kd2bd/predict.html.

Also, new Linux version is currently being prepared for release as well. (KD2BD)

**

INTERNATIONAL - SOUTH AFRICA: NO HT’S IN THIS CAR

Radio Amateurs in South Africa can no longer use a hand held radio in a vehicle unless its attached to a hands free operating system. This is the result of a new law that says that no person will drive a vehicle on a public road while holding a cellular telephone or any other communications device in one or both hands.

To operate mobile, hams and non hams alike now must use a radio permanently mounted in the vehicle and adapted to hands free operation. The law permits mobile radio operators to use such devices as a permanently mounted microphone and speaker or other specialized gear to comply. (SARL, Q-News)

**

INTERNATIONAL-UK: MARCONI 100TH ANNIVERSARY

The 100th anniversary of the reception of the first trans-Atlantic radio signal by Guilermo Marconi at Signal Hill in St. John's, Newfoundland, takes place on Wednesday the December 12th. In celebration, a number of United Kingdom special event stations will be active to commemorate the event.

Most of the operations will take place on the 12th of December itself. Even Great Britain’s Radiocommunications Agency is getting into the act. It will be operating GB100WT from its laboratory site at Whyteleafe, Surrey, during part of December including, they hope, the full 24 hours of the 12th of December. The Radiocommunications Agency expects to be operational on the High Frequency bands as well as 2 meters and 70 centimeters. The station will be operated by Radiocommunications Agency staff in addition to members of local radio clubs and will welcome QSOs with stations worldwide. (RSGB)

**

RADIOSPORTS: WRTC-2002 REMINDER AND UPDATE

A reminder that the next World Team Radiosport Championship will take place next July in Finland. The games will be hosted by the Finnish Amateur Radio Society and the Contest Club of Finland. WRTC brings together over fifty two man teams made up of the best contest operators from around the world. The actual on-the-air competition pits two man teams operating from a common geographic area using identical equipment, power and antennas.

To get a good idea of what goes on at the World Radiosport Team Championship games, film-maker Dave Bell has produced a half hour documentary video titled “The Ham Radio Olympics.” Its priced at only $19.95 and is available on video CD or VHS tape from the American Radio Relay League. More information is on the web at www.arrl.org. (WRTC, ARRL, W6AQ)

**

DX

In D-X, word that wore torn Afghanistan is back on the air following the ouster of Taliban forces from most of that nation. Q-News Graham Kemp, VK4BB, is back with the details:
--
Graham Kemp VK4BB:

“World traveller Peter Casier, ON6TT (5X1T), has been in Afghanistan for the last few days and has now obtained permission to operate in this worn torn nation.

On November 21 he was QRV as YA/ON6TT/M operating in a convoy. The foreign ministry of the Islamic Republic of Afghanistan (Northern Alliance) issued the call YA5T, which can be used on all bands by Peter, ON6TT, Matts, SM7PKK, and Robert, S53R.

Wayne Mills, N7NG, will have to look at the permission, once it is received. His initial reaction was that it should be good for DXCC. Peter will hopefully be contacting Wayne and submitting the documentation. Meantime, look out for these three operating as YA5T.”
--

And late word from the ARRL’s DXCC Desk is that it has already received acceptable documentation for YA5T and has approved it for credit. (Q-News)

Several DX newsletters report that N6TJ is active as ZD8Z from Ascension Island again. He is expected to be there through the 18th of December. QSL as directed on the air. (OPDX, Modern DX’er)

Lastly, word that high seas have forced the Ducie Island DXpedition team to abandon its already-delayed effort to reach that DXCC entity located in the South Pacific. According to the RSGB, the team was some 80 nautical miles from its destination and facing high seas when the decision was taken to turn around and head back to Pitcairn Island. (GB2RS)

**

THAT FINAL ITEM: STRANGE SCIENCE - FAT BIRDS FLY BETTER

About twice a year we bring you stories about radio tagged migratory birds. In most cases its those ever elusive Burrowing Owls. Now we have a totally different kind of bird story. It still involves radio tracking, but this time to see if bigger birds or smaller birds have a better chance to survive in flight. Amateur Radio Newsline’s Joe Moell, KO0V has more:

--
European scientists have discovered what seems like a contradiction about migrating birds. They found that the fatter the bird, the more efficiently it appears to fly.

Researchers at Lund University in Sweden have studied several small species including the Red Knot. In our hemisphere, these 20-ounce wading shorebirds travel 18,000 miles every year, to the tip of South America and back to the Arctic. On the way north, they stop on the shores of New Jersey to feast on the eggs of horseshoe crabs, to build up energy for the last 2000 miles of their northward trip, which they make non-stop. On these binges, the Red Knots can double their normal body weight.

Over the past few years a number of European Red Knots were radio tagged and tracked by the Swedes as they prepared for a similar trip between the British Isles and the Russian Arctic. The study indicates that building up of fat deposits to be burned as fuel during the migration is more than worth the energy that it takes to carry the additional weight. The heavier birds apparently use their muscles more efficiently. Just why this is so remains a mystery. Even stranger is that the results seem to 'fly in the face' of a central theory of aerodynamics -- no pun intended of course.

So what does this have to do with ham radio? Well, it points out that research always seems to yield unexpected results, and it gives me a chance to remind you that dozens of ham operators in western states are listening for the VHF radio tags on endangered Burrowing Owls this winter. You could help out too. Find out by visiting my Web site -- www.homingin.com. Who knows, maybe a ham will make a similar startling discovery about the migration habits of these unique critters. That's homingin -- one word -- for the Web site, homingin.com.

For Amateur Radio Newsline, in southern California, this is Joe Moell - K-zero-Oscar-Victor saying, "no jokes about birdbrains, please."
--

All of this really goes to show that the more mankind uses science to discover the secrets of Mother Nature, the more amazed man is at what he learns. (Ecology Today)

Ummmm, what part do you not understand? The lower paying jobs attracts the lower brain functioning people . The higher educated/skilled/motivated people work someplace else. You know, the ones that couldn't/wouldn't go to school or if they did, put in the minimum amount of effort. Ya know, the ones that figured out how to scam (welfare?) the system and squeak by with the minimum amount of effort. Of course there are the educated idiot people in life as well. RS employment, like allot of other places is just an extension of this. Hard finding good help at any price and even harder to get rid of the poor help after you got them. Sounds like you have your share. The RS stores in my area are not as bad as yours. They are not techie types, but at least they will get you to the section of the store where the parts you request are possibly located. Then they will take your money and make correct change.

Hi Dave.

You got a bunch of replies, but I think none of them really gives You the easiest answer...
First: I will not use American units. It's to tomplex to make head calculations in (or, I am not used to them..) 100 feet is approx 30 mtrs. This is good!
First, You buy or build an 1:1 balun. Your neighbors will like it (less TVI), and You will like it (no RF on rig chassis). If You use a real balun, instead of "poor mans balun" (i.e. coax cable coil), You will get the advantage of a symmetrical radiation pattern from Your antenna.

Well, first You cut out Your elements. For 20 m, approx 2 x 5 m, for 17 m approx 2 x 4.25 m etc (better calculate them more exactly). You'd end up with 10 wires. Connect all to the balun, forming 5 dipoles connected to the same balun.
Now, make 8 plexi-glas spreaders. Approx 0.2 m length that's about 8". Drill a hole in each end, and attach dipoles together, so that they will form a 20m dipole, with the higher band dipoles hanging beneath, one under another.
You will need 4 guy wires, 2 to bear the weight of antenna, 2 to ensure that the dipoles are evenly "spread-out".
This will be easier to tune than the "Rotor cable" antenna (according to the same principle). For the tuning, an ordinary SWR-meter can be used.

Now, why settle for 5 bands? A dipole working on f MHz, also works (un-tuned!) on 3 x f MHz. If You cut dipoles for 40, 20, 17, 12 and 10 MHz (the same amount of dipoles = the same amount of work) it will work nicely on 15 mtrs also!

(Remark:The relationship between 30m (10.1) and 10m (28-29.7) indicates that a dipole for 30 m perhaps could be used on 28 MHz phone, dipoles tend to be quite "wide" on 28, so perhaps... Anyone tried this?? And, if and when You get 5.4 MHz in the States, the people with a 160m dipole already got an antenna...)

I used this set-up for many years (for 40/20/15/10, 3 dipole set-up) and it worked super. No tuner, SVF< 3.0 on all 4 bands... Simple, easy and cheap.

Hi,
I'm adapting my 40 metre 3 vertical "end-fire" system for use on 28 MHz for this weekend contest,
I've spaced the verts 8 feet 4 inches apart in a triangle and am imposing a 1/4 wave (electrical) delay
line in the shack. The query is... I'm using Butternut HF6Vs which are 3/4 wave antennas on 28MHz,
is there any problem in using 3/4 wave antennas spaced 1/4 apart? - I don't think there is but...
thanks in anticipation

Especially since the identical function can be performed by varying the
length of the ladder-line. It is sure easier to tune an antenna system
at the transmitter end than at the antenna end.

The .66 is a velocity factor for coax. You would just cut to a 3/4
wave. But a 3/4 wave is not a very good antenna for those bands. Yes,
it would likely be better than a short duck, but you would probably be
better off with a good 1/2 wave design. And that would not be easy to
homebuild as it needs a matching section. There are commercial models.
If I were to make an antenna for an HT as a cheapy special to avoid
spending money, I'd probably just make a 1/4 wave. MK

I don't think he's talking about frequency per se, George. He seems
to be talking about the impedance variations related to frequency
changes. For instance, a choke with 300 ohms of choking impedance
performs well in a 50 ohm environment but doesn't perform well in
a 3000 ohm environment.

There is a problem using 3/4WL verticals on 28MHz. Above 5/8WL, the
radiation pattern becomes higher angle. If there's one HF band where
you don't want high angle radiation, it is 10m.

I use gas arrestor blocks on my control and rotor cables at a
common ground point where the coax, control, rotor and ground
rods all share a common grounding window--outside of the shack
before the cables enter the house.

The idea isn't so much as to keep all of the voltage out of the shack,
but to keep all of the lines at nearly the exact same potential during a
strike to minimize current paths through the equipment.

You might try the Polyphasor website for protectors that could
be used on your rotor cables.

12/14/01

Hi All,

Raw wood (untreated with paint, varnish, etc. absorbs moisture and herefore will have an effect on an antenna mounted in an attic. Of course, snow on a roof will play havoc with the signals Even a roof made wet with rain will attenuate the signals from some directions.

Hey, if that's your only choice, go with it. I't better than your wet finger for an antenna.

If you live in the desert SW of the United States this is no problem. If you live in the NW, it can be a big problem.

Regards,

Don

>
> Roy Lewallen, W7EL

I did too. And you will notice some very strange effects when trying
to tune them. It's much easier to spread them apart a bit. Right
angles is best and has almost no real interaction as far as tuning.
I've had legs fall down for one band, and notice no difference on the
other if they are at right angles. One strange effect I've seen is
tuning a higher band. Say 40 meters when you also have 80m legs. I've
seen cases where you have to add wire to go UP the band. Really
strange. And like you say, when you have this condition, the bandwidth
will be narrow. You can get them tuned, but this is not for the faint
of heart. Expect to spend a lot of time tweaking them up. If if you
have them spread apart a bit, they act fairly normal and is much
easier. To work all bands like he wants to do with a single wire, I'd
rather get/build a tuner and use ladder line to a single dipole. Or
just stick to one or two bands with a coax dipole. Or he could use the
Cecil method of tuned ladder lines to a single dipole. The rotor cable
dipole will radiate pretty well, if you can get it tuned. I can say
that much for it. It's just getting it tuned. MK

Hi Will

There is a company that makes a hand protectant in two forms, I don't recall but it may be named 'Chap-Hands', in any case, of their two formulas, one is for working in a greasy environment, like an auto-mechanic, the second, which is almost impossible to get off your hands is for working in a wet environment, such as a floral arranger or fish cleaner, hi hi.....

It comes in tubes and the one for a wet environment dries quickly and repels water excellently. It would be a lot harder to put on than a spray silicone, but I doubt it would ever wear off.

I was thinking of something else...With those close element dipoles I would usually have to offset the feedpoint to get a decent match for each band. Sort of like adjusting a gamma match. Almost never would be perfectly centered. You have such weird impedances that you almost always need to offset the feed a bit to get a decent match. I'm talking in inches. And you have to go from low to high in freq. You'll be pruning until 2007 if you go from high to low . MK

|Hello Wes,
| I choose to put technology to work for me just as Hams have always
|done for decades within the scope of their abilities. The "old way" is
|rarely the best way Wes...unless you are talking about 50 year-old
|hooch...

I don't reject new technology. I spent 33 years of my life designing, testing
and supervising the construction of, state-of-the-art tactical missiles. I was
using and programming an H-P computer, running HP Basic, to build automated test
setups when the only DOS PC in the building was located in the engineering
manager's office.

|
| Hams are by nature innovative and are always looking for and / or
|creating better ways to do things.

Yeah, I "innovated" a two-meter station that except for 50 feet of RG-17 was
entirely designed and built by me. Antenna, crankup mast, rotor, transmitter,
receiver, etc. With this station I made my first EME QSOs. A friend and I were
the first hams in AZ and maybe much of the southwest to operate SSB on VHF, when
SSB was proven to be "a better way" than AM.

| Without using DX cluster spotting services one finds themselves at the
|bottom of the "DX Feeding Chain"

Somebody has to be first to hear the DX station and generate the spot. I
believe that proves my point that DX can be found and worked without using
clusters. I also believe that puts one "at the top of the feeding chain." It's
waiting for the spots that keeps you at the bottom.

World-wide internet spots can be of interest in seeing where the propagation is,
just as the NCDXF beacons are similarly useful. Online DX newsletters and QSL
info services are also useful. So I don't reject out-of-hand some of these
tools. I simply contend that a cluster is not "vital" to the ability to work
DX. I do not use a cluster and I still find and work DX.
|
| If that is where you want to wallow then more power to you......

Well, I'm a pretty casual DXer. If I was a "real" DXer, I wouldn't be wasting
my time writing to you. Nevertheless, you claim 299 on your web site, I'm
"wallowing" around at 305, not counting deleted countries, but counting
4L4FN/P5. You do have him don't you? Or did you wait until he was spotted and
then found the pileup to be too big to bust with your "official" W9INN dipole

<g>.

BTW, the "biggest" HF antenna I've ever had is the homebrew (is that "innovative") 20 meter beam at 45' that I currently use. Viewable on my simple home page at:

http://users.triconet.org/wesandlinda/

Cheers,

N7WS

Wax would seem to be better since water wouldn't stick to it well. I don't suppose that RainX would adhere to ladderline. (I swear by that stuff on my windshield). Why not run it inside plastic or PVC tubing? That would keep the water from between the conductors.

DX clusters are the worst thing ever to happen to ham radio. Just listen (don't talk, there's enough QRM) to the nightly abomination when the P5 comes on 10 meters. What a sad state of affairs.

Isn't "the hunt" interesting? Just sitting back while your cluster software tunes you to the DX is being pretty lazy. Maybe that's why all the "wrong VFO" callers - they aren't paying attention to what they are doing because the software "does it all fo them" (albeit poorly)?

Hi Gary,

I would suspect any application of a surfactant given that even relatively benign water offers so much loss.

In other words, this slick product works to shed water, but that says nothing of its electrical qualities (if they could in fact be called quality and not hazard).

Some of what you describe sounds like it has a high volatility content (like benzenes or alcohols) which can seriously change the insulative properties of plastic (in fact de-plasticising it), causing crazing and leading to water absorption.

Most will be familiar with the development, recommended construction & use of large octogonal single HF loops of copper pipe (etc.). Has anyone heard of, contemplated or have any insight concerning a spaced multiple-turn version of this - perhaps physically analagous to a tank coil built by Godzilla - for even more gain & breadth, and at lower HF freqs?

Hello Paul,
It seems like any mention of augmenting one's DX searches with a spotting cluster or web site immediately brings forth messages like "sitting back and letting the cluster do all your work" . Well this is not the case at least for me. I run the cluster through DXBase 2002 so that if a new one gets spotted I am notified. While that goes on in the background I am "searching and pouncing" just like the "old-timers" would like me too.

Often I am working 2 or 3 DX stations at a time. How can that be? If there are pileups and if I don't get through on the first 2 or 3 calls I write down the call and freq of the DX station and move on to another one or two doing the same with them if needed. Then it is a simple thing to check my sheet and tune the ones back in I didn't get on the first few calls. This works a treat....I just hopscotch between 3 or so stations until I get them or they fade or go qrt.....it is really quite effective...

So..there is no need to ridicule anyone for using the cluster or working DX however in the hell they please....

Hi Don,

I live in rain city. On page one of today's paper: 1.48 inches of rain in 12 hour period (2.15 inches nearby) or about 7 to 10 times the usual daily amount (0.2 inches each and every day, day-in-day-out, ceaselessly, unremittingly.... "it was a dark and stormy night").

This is also wood country (the two go together). Here in this group we often speak of the horizon or line-of-sight contact. These are academic artifices. In tree country the only horizon I see is the jagged peaks of volcanoes (if they are not covered by clouds) over the tops of trees. Line-of-sight is maybe twenty feet before the predominate color is either bark brown or pine needle green.

No problems to speak of.

Most lumber contains about 20% water by weight, furniture grade wood is dryer at about 10-15% water. Fresh cut wood is substantially higher (as is uncut wood, naturally).

Lumber, in a wet climate (or dry for that matter) exhibits a variation in water content that follows the humidity. This is called Equilibrium Moisture Content. For a ï¿½10% variation in Relative Humidity (say from 40% to 60%) the Equilibrium Moisture Content

changes by only 3% (not 20).

Strange thing about climate is that for as much rain that has fallen the Relative Humidity is quite dry - currently 43%. Humidity is far more impacted by heat which increases the water carrying capacity of air. This is why your lips chap in winter.

The upshot of this all, is that wood found in a domicile is protected against direct contact with water and its variation in water content is very slow and very minor. If it presents any problem, it is a relatively constant problem that is resistant to both improvement and further degradation.

The real crux of my comment is you can tell as soon as some juicy DX station shows up on the cluster because things go to hell on the band. It turns into utter chaos. People start chattering away on the wrong VFO (I assume they failed to notice the station is working split). Then the "cops" chime in. And then I tune out.

3951. Quad vs. Yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-14 20:55:11 UTC
From: bill@hovac.com
Message-ID: <c00cc1cb.0112141255.529627a6@posting.google.com>
Source record: 152804

Hi to the group,

I presently have a 4 element (trapped) 10-15-20 tribander. I am considering a 5 band 2 element quad (10-12-15-17-20).

I have read that the quad performs better at lower heights than a yagi and doesnt' receive as much "noise" as the yagi. My antenna is at 43 feet.

The gain on both antennas is very close.

The only negative I can see of the quad is it doesn't handle bad weather as well as the yagi. However, I was monitoring a QSO in which one of the hams was from Alaska. He was using a quad and said it held up to the wind and ice just fine.

I would like to hear from the group's experience and knowledge of the pros and cons of these two antennas in comparison to each other.

Thanks and Happy Holdiays!
Bill

Roy, W7EL wrote:
"Why does everybody fuss with the cores and things?"

Good question. Slipping cores around coax or wrapping turns of feedline around cores or a big coil form works over a wider bandwidth than a resonant line does. Amateurs are interested in more than one spot on the dial in most cases.

Best regards, Richard Harrison, KB5WZI

Hello Paul,
Your comments of course are correct. But don't blame the cluster spots for human behavior patterns. I have to agree with you...often times the apparent mentality in a DX pileup is like a pack of hungry dogs salivated and fighting over the same piece of meat. But hey..if you want the DX in your log what are you going to do?

One of the DX Tips on the DX Page of my site offers a remedy for such a scenario....

3956. DX Packet Cluster Controversy

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-14 21:50:01 UTC
From: AC6V <ac6v@amsat.org>
Message-ID: <3C1A7408.A6F530D6@amsat.org>
Source record: 152809
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment

To add fuel to the flames, remember that before the days of Packet Clusters there was DX clubs that had all the members phone numbers and "one ringers" were common when rare DX appeared.

Then came the DX repeaters (2M) where DX announcements were made 24 hours a day!

And since day one (maybe later) DXers subscribed to DX News Letters to get the latest DX operations - freq and time.

So don't tell me about OT's that found all there own DX, but some did.

But obtaining Honor Roll without DX Packet Clusters --- good luck Charlie!! Better quit work, get a divorce and stay up all night. But I'm sure many did.

Then there is DX Nets -- No Comment

It seems to that this could be taken a bit further. Search the band through a computer controlled radio. When a signal is detected, the computer would lock onto that frequency and send a signal. On receipt of a reply, it would log the station and move on. That way you could watch TV, mow the lawn, or whatever and just check your computer from time to time to see how its going.

Actually I would think that the clusters would prevent more "wrong VFO" type
people. Most spots say "up X". More it is just poor operating. Not the
cluster itself.

Kent, K9EZ

PS - I am not even trying the P5. It will be there. And it will come back
after the first of the year. We will all get the chance. Though we may not
be first.

Hello Mark,
Firstly, TY for your reply.

id rather a 3/4 wave to get a bit of gain from it and its a straight cut whereas the 1/2 wave has [as you say] hi Z feed problems.. from a homebrewer point of view its much more mechanically stable to build a 3/4 than a 1/2 cause of the Z trans needed.. In Aus [VK] 1/2 & 3/4 wave commercial start from $70 AUD [$140 USD] so home brew is big here.

I considerred a 1/4 wave but its range here is poor [vast mountainous landscapes] plus the fact my HT came supplied with one.

But anyway i now know what i needed to find out [free space],just cut it at the right dimension....

Ive built a few before but never botherred with free space stuff [didnt know then its only coax] i just cut it etc. but as my HT is new i thought id do it properly..

Cheers Mark and TY for informing me ok.. Merry Xmas.. Rod

For Crissake...leave RadioShack alone. If you want decent fried chicken, you go to a fried chicken place and not McDonalds. If you want electronic components, go to a place that deals with them.
If you even want a cell-phone, go to the source. If you want a TV or stereo or computer, go where they specialize in them. If you want a plastic helmet with a blinking light and siren, Radio Shack can't be beat.

Hello Rod,
Thanks for posting your perspective on this "controversy". I know that even with my simple station my country count skyrocketed when I first connected to the N7CIX cluster (Phx,AZ) via the AA7MH repeater on our local Spruce Mt. (Prescott,AZ) It was and still is a great aid....

I would only like to add that even though one can receive the spots that does not mean one's station is up to the task. There is nothing "automatic" about getting the station in the log just because one has been notified that the DX is qrv....

"You still gotta have the Fire to the Wire" and some operating skill for good balance.....

Roy,

I have heard of this oval stuff you suggest. Kind of linke a hybrid of coax and twinlead. In fact, if I remember correctly, it goes by the trade name "Twin-Ax." How will it perform compared to Ladderline, WRT high-SWR & losses on many bands, wet performance not considered, for the moment? I may need to use it, after giving the ladderline the old college try. Any idea where I can get some, ideally local retail (Did you say you dwelt in the Emerald City?). Thanks.

3976. Antenna tripod installation on a roof?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-15 06:28:44 UTC
From: googlyelmo@earthlink.net
Message-ID: <3C1AED90.96C84457@earthlink.net>
Source record: 152729

I am putting up a single dipole (maybe another wire antenna or two later, but nothing heavier), supported by a 20' (2 sections) galvanized mast atop my roof. The mast will be supported in turn by a tripod. I seek advice on the most secure way to attach the tripod to the roof. Each leg has three bolt holes, and the tripod comes with 6 (!) 3" lag screws. I question whether the 3" lag screws are robust enough, even if I use 9, rather than 6, of them. Am I right? Radio Shack sells a little appliance that fits on the peak of a roof, and accepts the base of a mast. It is meant to be used alone, with guy wires. I thought I might add this piece of hardware to the installation to beef it up. Is that necessary, or is there some better way perhaps reinforcing a tripod and mast. Of course I will use guys, at least 4, using 6 x 18 AWG galvanized wire. The roof is covered in asphalt shingles, then tar paper, and underneath it is 3/4" tongue & groove board, circa 1928. The roof is in excellent overall condition, including the shingles. I don't know if my cheap and cheezy studfinder gadget will work to find the joists, so I need alternatives for locating suitable, sturdy points to place the fasteners. I want to be sure also that I don't cause any leakage problems (I live in Seattle, so a leaky roof is a *big* deal). I thought that if I applied some RTV silicone sealant around/on/over the tripod feet and bolts that would ensure a dry attic. If I can go further, within reason, let me know how to proceed. Thanks,

>I thought that if I applied some RTV silicone sealant around/on/over the
>tripod feet and bolts that would ensure a dry attic. If I can go
>further, within reason, let me know how to proceed. Thanks,

I have a 10' tripod on the roof. It carries a Ham IV rotor with a
TH6DXX yagi on it. The pole that holds the Yagi extends through the
yagi 10' high and has a CCraft 2m Boomer on it and a Ringo at the top.

My tripod has three guy wires and is screwed into the roof with lag
screws. I went to no trouble to find studs or use backing plates.

It has been there for 10 years in winter New England winds and snow
loads, ice storms and occasional high winds, (the highest was 90 mph
gusts). It has not moved, damaged the roof or caused the roof leak.

No, what I was referring to is twinlead, but with the dielectric in a hollow oval shape. It has no shield like twinax. The advantage of the oval shape is that there's no dielectric, or water or other lossy things, in the space directly between the conductors where the field is most intense. I think the space is sometimes filled with a foamed dielectric material to prevent water ingress. TV twinlead isn't often used any more, so the oval variety would probably be hard to find these days.

I live near Portland.

HAM RADIO IN SPACE: ANOTHER TOURIST TO THE ISS

Could there be another ham radio space tourist headed to the International Space Station? Well the ham radio part is not yet known, but NASA and its partners in the I-S-S have agreed in principle to let a 28-year-old South African become the second paying tourist on the orbiting outpost. Amateur Radio Newsline's Roy Neal, K6DUE, has more:

--
The International Space Station may get its second paying customer next April. South African businessman Mark Shuttleworth has signed a contract with the Russian Aviation and Space Agency to buy a seat.

Kirsten Larson, a spokeswoman for NASA, has confirmed tentative agreement with the various space agencies that would allow him to fly. Shuttleworth is to go up to the I-S-S on a Russian built Soyuz. The arrangement was negotiated by Space Adventures, an American company in
Arlington, Virginia. That's the same outfit who made the arrangements for Dennis Tito, the first space tourist. Tito, KG6FZX, was allowed to get on the ARISS radio while he was up there and created quite a stir on 2 meters.

Mark Shuttleworth is not licensed at this writing but has said that he plans to be more than just a tourist looking back at earth. He has said he will take part in a number of scientific experiments. It's not too far fetched to suggest that he may be talked into taking the time to get a ham license, time permitting, as he trains for the flight. He will have to train extensively to meet rigid standards before getting final approval. If all those ifs go together, next year ham radio may have its second tourist in space to talk to and about.

For the Amateur Radio Newsline, this is Roy Neal, K6DUE

--

Ironically, the proposed date of Shuttleworth’s visit to the I-S-S would be almost exactly a year after Dennis Tito made his visit. That flight last April raised objections at the National Aeronautics and Space Administration about his fitness and training. No such problems this time around. (ARNewsline(tm) from various sources)

**

HAM RADIO IN SPACE: ISS CELEBRATES MARCONI

The International Space Station's returning skipper marked the 100th anniversary of the first trans-Atlantic wireless contact by chatting with youngsters at the exact spot history was made. The contact took place on Wednesday, December 12 th as the station, docked with the shuttle Endeavour soared over the North Atlantic, off the Newfoundland coast.

During the short QSO, outgoing station Commander Frank Culbertson, KD5OPQ, used two meter F-M to speak to teen-agers gathered at the Signal Hill National Historic Site of Canada in St. John's, Newfoundland. Culbertson managed to answer 10 questions from the students before the I-S-S flew out of range.

One of the questions asked of Culbertson was how he bathes and brushes his teeth in orbit. Another was how he gets along with his crewmates in such close quarters, and whether he misses home.

His answers? KD5OPQ told the youngsters that uses damp cloths and no-rinse shampoo, that he swallows the toothpaste since there's no sink, that he gets along fine with his colleagues, and sometimes does wished he were home.

The contact was facilitated by ARISS – Amateur Radio on the International Space station as part of an educational program at Signal Hill celebrating Guglielmo Marconi's success in receiving a wireless signal. That transmission came from Cornwall, England, on December 12, 1901 and consisted of nothing more than three dots. That’s the letter S transmitted in Morse code.

For the Amateur Radio Newsline, I’m Mert Garlick, N6AWE. Jim. (AMSAT-BB, AJ9N and ARNewsline(tm) from published news reports)

**

HAM RAIO IN SPACE: NEW HAMSAT IN 2002

Look for a new ham radio satellite to be launched in 2002. The new bird called Kolibir-2000 is a Russian and Australian School joint scientific and research microsatellite.

Miles Mann, WF1F, of MAREX reports that the new bird will be taken to orbit during a Russian a cargo mission to International Space Station. Kolibir-2000 will then stay in space attached to a remote port before being launched. (AMSAT-BB)

**

ENFORCEMENT: FCC SAYS IT WILL NOT INTERVENE IN ALABAMA NETMESS

The FCC's Enforcement Bureau has in refused to take sides in a dispute between several nets wanting to use essentially the same frequencies on the 75-meter band. The bickering had pitted the Alabama SKYWARN Net , the Alabama Traffic Net, the and the Country Cousins Net against a newly formed informal gathering of hams in another loose knit network.

The Alabama SKYWARN Net, the Alabama Traffic Net, the and the Country Cousins Net have long operated between 3.965 and 3.970 MHz. The informal group decided to try to use the same spectrum. That's when the dispute erupted and everyone wrote to the FCC. After reading the complaints, Special Counsel for Amateur Radio Riley Hollingsworth told all four that it was really up to them to solve the problem, and to do it without breaking any rules:

--
Hollingsworth: "We issued a letter to all parties in a 75 meter interference dispute and we warned all parties and [also] attempted to explain what incidents were enforcement problems and what activities were just poor Amateur practice and degrading the entire service."
--

Hollingsworth's response went to Henry Willmon, WA4GQS, Sal Viglione, W4SAL, Jeremy Jackson, K9CNI, and Alabama ARRL Section Manager Bill Cleveland, KR4TZ. (FCC, RAIN)

**

ENFORCEMENT: FCC WARNS UNCOORDINATED REPEATER OWNER AND HIS USERS

The FCC has again written the operator of an uncoordinated Southern California repeater about ongoing interference. Again the FCC's Riley Hollingsworth:

--
Hollingsworth: "We issued a second and final warning to a Los Angeles California licensee; Angos Winke, KC6OKA, about operating an uncoordinated repeater that is interfering with the coordinated repeater W6IER. {This is] a repeater operated by the Inland Amateur Radio Club.
That licensee will also be receiving a letter from the Los Angeles office prohibiting him from using Automatic Remote Control for the repeater."
--

That means the system can only be on the air when there is a control operator present and that ham will be held responsible for any interference caused by the repeaters transmitter.

But that's not all. The FCC has also sent letters to several users of the uncoordinated repeater a warning of their own:

--
Hollingsworth: "We sent warning notices to five licensees in the Southern California area concerning operation on the coordinated repeater I mentioned a moment ago: The one that is causing interference to W6IER. This is in addition to the action mentioned about taking the licensee off of Automatic Remote Control. And we warned them about interference to the coordinated repeater."

--

Each of the letters says essentially the same thing. That the FCC has information indicating that interference to the repeater has been occurring from each of the users stations through a repeater on the same frequency as W6IER, but one that uses various call signs. It warns the users that continued interference to the W6IER repeater could result in a monetary forfeiture of up to $7,500. Also, depending upon the evidence, revocation and suspension issues might also be warranted. (FCC, RAIN)

BREAK 1

This is ham radio news coming to you from the United States of America. we are the Amateur Radio Newsline, heard on great bulletin stations around the world, including the Broward Amateur Radio Club net serving Ft. Lauderdale Florida and vaccinate.

(5 sec pause here)

**

FCC: FCC LIBRARY CLOSED TO THE PUBLIC

Effective December 5 th and until further notice, the FCC Library is closed to the public. This action is said to be necessary because the Commission is using a portion of the library to temporarily house FCC employees. More information is on the web at http://hraunfoss.fcc.gov/edocs_public/attachmatch/DOC-218204A1.doc (CGC Communicator, FCC)

**

RADIO DISASTER: MISSOURI TOWER FALLS

A 1,627-foot broadcast tower near Springfield, Missouri toppled to the ground Friday morning November 30th from the weight of a foot of ice from several days of freezing rain. According to a report from KYTV the 33-year-old tower collapsed on itself like an accordion.

No one was around and the damage was confined to the area around the transmitter building at the base of the tower. No engineers were in the transmitter building when the accident occurred.

KDEB television and KTXR-FM were the resident broadcasters on the tower which was owned by American Tower of Boston. The total height included the 1,560-foot tower plus the antenna on top of it. The loss could cost American Tower or KDEB millions of dollars. (Listener reports)

**

HAM RADIO HELP: THANKSGIVING BASKETS

On a much happier note, a group of Indiana hams make the news this week for their generosity. Amateur News Weekly's Jack Parker, W8ISH, tells us that the radio amateurs recently brought some holiday cheer to those who might not otherwise be able to celebrate:

--
Thanksgiving came early for many residents of Hamilton County. A half dozen Hamilton County Amateur Radio operators helped to deliver over 200 Thanksgiving food baskets to shut-in residents across the county.

This is an annual project headed up by John Wadsworth AA9KB. The food baskets are arranged by the local chapter of the American Red Cross.

Reporting for Amateur News Weekly, I'm Jack Parker, W8ISH.
--

Jack says the Hamilton County hams will be back again next year. (ANW)

**

HAMVENTION 2002: FORUMS SCHEDULE ANNOUNCED

If you are thinking about attending the 2002 Dayton Hamvention, then go its website and click on the Forums area. Forums Chairman Jim Ebner, N8JE, says that the initial schedule for next May's Dayton Hamvention group discussion sessions is now on line and Amateur Radio Newsline's Don Wilbanks, KC5MFA, takes a peak:

--

As previously announced, the theme of the 2002 Hamvention is Emergency Communications. In keeping with the theme, some of the highlights include Gordon West WB6NOA explaining how use of the Global Positioning System. Gordo will also show how it offers hams the ability to know where they are and describe where they are to better than a foot. That's very important information to have on hand when working an emergency situation.

But that's not all. Also on hand will be John Mc Hugh, KU4GY, the Coordinator for Amateur Radio National Hurricane Center, W4EHW. Mc Hugh will show the volunteer public service work of the gang at W4EHW, and the inside workings of the National Hurricane Center in Miami.

KU4GY will also detail two exciting projects called CARMEN and CWOP that they are working on in conjunction with NOAA. What are they? You will have to attend his session at Hamvention 2002 to find out.

Vermont's Mitch Stern, W1SJ, will also be there to talk on techniques used by the best operators involved in emergency communications. This session will also include information on the proper way to communicate during emergencies. Also hosting a session will be Mid-Cars on the importance of mobile to mobile and mobile to base communications are during emergency times.

Amateur Radio Newsline will also be there once again hosting the Live Town Hall Meeting. Bill Pasternak, WA6ITF, will moderate a session on Ham Radio Emergency Communications in the 21st Century titled Looking to Apply What We

Have Learned From the Past.

And also look for the most popular sessions including Carole Perry’s Youth Forum and Joe Eisenberg, K0NEB, with the latest in kits and how to build them.

This and a lot more happens May 17th 18th and 19th at the HARA Arena in Dayton Ohio. We will see you there.

For the Amateur Radio Newsline, I’m Don Wilbanks, KC5MFA.

--

Want to know more? The latest information on Hamvention 2002 is always on the web at www.hamvention.org. (DARA, ARNewsline(tm))

AMERICA AT WAR: RELIEF FUND GROWS FOR WTC VICTIM'S FAMILIES

A relief fund, established to benefit the families of the six broadcast engineers and technicians lost in the collapse of the September 11th World Trade Center has begun providing aid to the families of those killed in the terrorist attack. Amateur Radio Newsline’s Bill Pasternak, WA6ITF, has the details:

--

The Portland Oregon S-B-E electronic newsletter says that soon after its inception the S-B-E sponsored fund began drawing the attention of individuals and companies from across the country. And as of November 1st, almost $50,000 had been raised to assist their families of those who lost their lives in the collapse of the World Trade Center.

The fund that was started by the Society of Broadcast Engineers and the Ennes Educational Foundation Trust. Initial checks to the nearest family member of all six men were sent by October 31st. Eventually every penny off the money raised will go to the families of the victims. This is because the fund is all volunteer. There is no overhead of any kind involved and there is also no restriction on how the recipient may use the money.

In Los Angeles, I’m Biill Pasternak, WA6ITF, reporting for the Amateur Radio Newsline.

--

If you are interested in contributing, checks should be made payable to the Ennes Educational Foundation Trust and mailed to the Society of Broadcast Engineers, Inc., 9247 N. Meridian Street, Suite 305, Indianapolis, Indiana 46260. Mark your check to the attention of the Relief Fund. (Portland SBE)

www.arnewsline.org.

**

TECHNOLOGY HONORS: FIRST ROTARY SPEED DIALER TO SMITHSONIAN

The developer of the first speed-dialer for rotary phones has finally been honored forty years after developing the unit. Pennsylvania inventor Vincent Iannucci spent two years developing the world's first speed dialer for rotary phones. The motorized device stored numbers and could dial up ten digits with the push of a button. It was nearly ready for the market in 1961, but production was disconnected by Bell Telephone Lab's after the development of touch-tone phones.

Iannucci put the prototype on his desk and used it until his own company changed over to the tone dialing system. He was going to throw it away recently, but a relative suggested he offer it to the Smithsonian. Now it's joining the museum's collection of electro-mechanical devices. (Science Online)

**

ELECTRONIC SAFETY: LIGHTING RECALL

A South Carolina lighting company has recalled over 10,000 fluorescent lights because they are improperly wired and pose a fire hazard. Progress Lighting, of Spartanburg, has received two reports of the fluorescent lights smoking and smoldering, according to the Consumer Product Safety Commission. No injuries have been reported.

The recalled fluorescent ceiling and bathroom lights were sold in various shapes. The label on the light contains the manufacture's name, the manufacture date, and a catalog number. Consumers are advised to using the recalled lights immediately and contact Progress Lighting. The company can be reached at area code 866-696-8593 between 8 a.m. and 5 p.m. EST Monday through Friday. More information is on the web at: www.cpsc.gov/cpscpub/prerel/prhtml02/02036.html (Press release)

**

HAM RADIO IN SPACE: AMSAT ON-LINE SURVEY

AMSAT-NA has developed a new on-line volunteer survey, designed to identify the interests and skills of those who may be available to directly help in efforts to develop the amateur satellite program. The survey was developed by a committee led by AMSAT North America
Vice-President and Government Liaison Perry Klein, W-3-P-K and is designed to be completed and returned on-line and takes only a few minutes to fill out. To request the survey, simply send a e-mail request to volunteer@amsat.org (AMSAT-NA)

**

HAM RADIO IN SPACE: AO-40 UPDATE

A scheduled attitude shift that is necessary to compensate for unfavorable sun angles, will leave the Oscar 40 satellite's antennas pointing away from earth until next spring. The adjustments will lead to a transponder shut-down period that could start as soon as late December. The satellite is currently in a long period during which earth eclipses the sun near perigee - its point closest to earth. Like most satellites, Oscar 40 relies on solar panels for its power. (AMSAT-NA)

**

DX

In D-X, Eddie Seymour, WB4MLE reports a really neat opening on 6 to Europe the morning of December 5th. From 1400 to 1500 U-T-C, Eddie, operating from grid EM72 heard or worked SP, DL,YO, 9A, S5, ON, OK, 4N, G and GW. This, as 6 meters defies the experts and stays the D-X band that just won’t quit. (VHF Reflector)

A new 2-meter propagation study beacon is being established at the Poldhu Amateur Radio Club in the United Kingdom. It is located 8 kilometers south of Helston in Cornwall and operates under the call sign GB3SSS will operate on 144.407mhz. Output power is 25 watts to two 8-element stacked Yagis beaming at 284 degrees. It is hoped to increase the power to 100 watts later. For further details please contact the beacon keeper, Mr. L Davey-Thomas, G3AGA, at his callbook address. (GB2RS)

Meantime, a bit lower in frequency look for the Council of Europe Amateur Radio Club. It plans to be on the air as TP5CE on the 14th to 16th of December, including the ARRL 10 Meter Contest. Outside the contest the main activity will be on all bands RTTY and CW. (GB2RS)

And PY8IT will operate as PYZ0FT from Fernando de Noronha between the 12th and 18th of December. He will concentrate on RTTY and PSK31. In both cases, QSL as directed on the air. (GB2RS)

**

THAT FINAL ITEM: AUDIO TIME TRAVEL

And finally this week, some words about time travel, Amateur Radio Newsline, our predecessor Westlink Radio and the audio history of ham radio since 1976. That’s the year that Westlink Radio started to bring you the sound of ham radio from around the nation and around the world. And believe it or not, we still have almost every newscast tape we ever aired. In fact, we are in the process of archiving them and we have found a lot of moments that should not ever be forgotten. Moments like this from November of 1983:

--
Audio Here: W5LFL from space
--

That was United States Astronaut Owen Garriott, W5LFL, making the first ever manned ham radio contact from space. Its a part of our history as hams and as a nation and needs to be remembered. So for the next few weeks we will let you relive the time that W5LFL spent orbiting the Earth and making ham radio

history. Here’s how.

As you know we recently began providing our newscast audio as a downloadable Real Audio file from our own website at www.arnewsline.org. All you need to do is click on the newscast number at the top of the page to reach the FTP site. Now, when you go there, you will also find another audio file outlined in bright green. Its called the Newsline Extra and all you need to do is to click on the word download and it will soon be in your Real Audio equipped computer, ready to play.

In the coming months as we archive more and more of our older Westlink Radio programs we will try to bring you the best of them. Meantime, we hope you will enjoy this December 11th 1983 ham radio in space retrospective hosted by Amateur Radio Newsline’s Robert Sudock WB6FDF and featuring the story of ham radio space pioneer Owen Garriott W5LFL. (ARNewsline(tm))

>Nevertheless, a silver plated stainless steel might be the really
>ideal antenna material. :-)

Forget silver plating, unless you like tearing up
large denomination bank notes and throwing them away.

Use galvanised steel wire or tubing. It works like
a charm.

Harry,
Take a tip from broadcast engineers. Use a i/4 wave
vertical with the base insulated from earth.

Measure the input impedance, both series and
parallel, at both frequencies.

Design a simple matching unit to connect to your
transmission line.

regards, Alan.

3985. Re: TJ Screwdriver antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-15 14:19:39 UTC
From: Gerald Schmitt <KK5YY@arrl.net>
Message-ID: <4jmm1uk1cpk0ev9mcl7fll9ki79p84u7qd@4ax.com>
Source record: 152738

Tom left Oregon and went into business with a fellow in New Mexico
The antennas are now sold by Nott Limited as the BB3. Tom has
sold his interest in the business.

The current people do repairs etc. if you need that.

While the term "Commode Choke" appears DOA, I can vouch for the fact that it is a very good idea to use one with a gamma-matched element. If you don't think there's current coming back on the shield because it's "grounded" to the boom at the feedpoint, guess again!

3988. Quad Advantages?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-15 14:59:45 UTC
From: Bill -N4DXR- <billNOSPAM@hovac.com>
Message-ID: <FuJS7.11113$r_.526001@atlpnn01.usenetserver.com>
Source record: 152741

Hi to the group,

I presently have a 4 element (trapped) 10-15-20 tribander at 43 feet. I am considering a 5 band 2 element quad (10-12-15-17-20).

I have read that the quad performs better at lower heights than a yagi and doesn't receive as much "noise" as the yagi. If this IS true then that seems to be the main advantage of the quad. The gain on both antennas is very close.

The only negative I can see of the quad is it doesn't handle bad weather as well as the yagi. However, I was monitoring a QSO in which one of the hams was from Alaska. He was using a quad and said it held up to the wind and ice just fine.

I would like to hear from the group's experience and knowledge of the pros and cons of these two antennas in comparison to each other.

Thanks and Happy Holidays!
Bill

3992. Re: Antenna tripod installation on a roof?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-15 15:15:13 UTC
From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3c1b6de2_3@news1.prserv.net>
Source record: 152745

Will:

With guy wires, the tripod will be primarily carrying downward forces, and should be adequate. Be sure to assemble the tripod to solidly support the bottom of the mast so it doesn't slip down and gouge the shingles. And, whose tripod is it? Rohn and South River both make tripods which are much more rugged then the RatShack device, but are not as easy to find for purchase. I have used RTV for sealant in the past, but now prefer the roofing cement (black, nasty stuff) for waterproofing. The RTV eventually lets go of asphalt shingles, and must be removed to redo it. With the roofing cement, just add a little more every 4 or 5 years, on the hottest day available. Make a little dam of it uphill from the feet, to channel runoff around the holes for extra protection from leaks, and put some in and around the holes when installing. A little creative shaping and installation of shingle pieces can fully protect the top of the foot and bolts from rain. Water is pretty predictable on a sloped roof. I would suggest using bolts and backing material, even a short piece of 2X4 inside, rather than the lag screws, if there is attic access. If you decide to use the lag screws, check the length carefully to insure that there are threads in the wood, and that they are not so long that the threaded portion goes all the way through. If the threads go all the way to the head, you are OK, but 3" usually have some unthreaded shank. Drill the correct size pilot hole, as wood that old is going to want to crack rather than compress as new timber does. Another reason to use bolts.

> losses on many bands, wet performance not considered, for the moment?

You don't need to go to Twin-ax as side-by-side runs of ordinary coax will
do. Side-by-side runs of 50 ohm coax gives 100 ohms Z0, 75 gives 150, 92
gives 184, etc. The problem is that you still cannot get the Z0=600 ohms
of open-wire line. The high Z0 is the primary reason that open-wire line
is less lossy than coax because it reduces the I^2R losses. If I could
build a 450 ohm or 600 ohm twin-coax line for a reasonable price, it would
certainly simplify my tuning method of varying the length of the feedline
to obtain a near perfect match.

Source record: 152752

Well, not exactly. Yes, the transponders will not be open for access.

The AO-40 beacon will still be working. In fact, the AO-40 Control Stations need volunteers
to capture this data to monitor the overall health of the satellite. Sounds like a great time to "tweak"
those AO-40 receiving systems and support equipment.

Remember that ISS Alpha will have the new antennas (UHF and S-band) installed over
the next few months ... time to check that Az-Ele rotor for computer tracking operation.

Source record: 152754

Technical question If an antenna is too short then I understand we would get impedance of r -j.Not that I am trying to do this . Transmitting 40 meter on a vertical less than 1/4 wave creates capacitive reactance

Why then would you add a capacity hat to electrically lengthen the antenna?

Is it because the additional capacitance is being added at the end of the antenna? I know it is impossible or difficult to add inductance at the feed point. This is just hypothetical.

Source record: 152758

Bill,
The 'worth' of a used tower is sort of determined by the
buyer, and the actual condition of the tower. If it's only
in 'fair' condition, what do you think it will cost to put it
in excellent condition? What ever that amount is, thats what
I would deduct from the asking price. It depends a lot on the
tower too. If it is a very well constructed tower, it's worth
more than one that's sort of 'flimsy'. All this is 'subjective'.
I have no idea if theres a 'used' price list...
'Doc

If capacitance is added the any AC circuit capacitive reactance goes
down.

Thusly, on your antenna you are reducing the capacitive reactance my
added more capacitance.

Manufacturer of the tower, where it is located (are there other buyers??), parts still available?? (Even Rohn has dropped a lot of parts for the 25G series!!). On the ground, or do you have to dismantle it? Lots of factors to consider.

Try eHams for some reviews of various models.

> 'Doc

It's not. The consideration is the Q of the base loading inductor and the losses incurred when placed at a high-current point, i.e. the low impedance end of a short (less than .25 wavelength) monopole.

I believe the question Jerry is asking is, "Why use a capacity hat?"

And the short answer: "(It) brings the current loop of the antenna as close to the top of the antenna as possible." "The current throughout the length of the antenna is maximized." (1994 ARRL Antenna Book, pg 2-38.)

This has the effect of raising the radiation resistance and hence the feedpoint impedance to an acceptable level (the r of r+jx) if the hat is properly designed. The addition of capacitance at the end of the antenna reduces the capacitive reactance of the antenna (remember x(c) = 1 / (2 * pi * f * c)) so less series inductive reactance is required to cancel it and bring the antenna system into resonance. At antenna lengths of 60 degrees or greater, the capacity hat alone may be sufficient.

The current flowing through the base inductor is less since the feedpoint impedance (r+jx) is increased. Resistive losses due to the Q of the inductor become less of a problem. If the antenna is a very small fraction of a wavelength, as in a mobile installation, base inductor Q still remains a significant factor since the radiation resistance (even with a capacity hat) is so low. Locating the series inductor away from the high current feedpoint (closer to the end of the antenna) decreases these losses due to Q. But inductive loading is best left for another discussion.

Or you can choose to shunt feed the antenna, eliminate the base insulator
and use a separate shunt feed network for each band - this was outlined in
one of the ARRL Antenna Compendiums.

>creates capacitive reactance

Yes the impedance at the base of your hypothetical monopole is
capacitive.
>
>Why then would you add a capacity hat to electrically lengthen the antenna?

One (slightly simplified) way of looking at it is thus: The monopole
can be thought of as an open-circuited transmission line. The
impedance of this line varies along the length because the ratio of
voltage to current changes along the length.

Intuitively, you can imagine that the current at the end of the
monopole must go to zero (near zero anyway) and with constant power
input this necessitates that the voltage must be greatest at the end.

Higher voltage and lower current indicates a higher impedance. The
converse is true at the bottom end where the current is higher and
thus the voltage is lower. The resulting impedance is easily measured
because the second terminal (ground) is handy.

This partly explains why a lossless 1/4 wave line terminated in an
open at one end presents a short at the other end. Because (it is
hoped) an antenna is not lossless (it radiates) the actual impedance
at the "shorted" end is higher and equal to the "radiation"
resistance.

If the monopole is shorter than 90 degrees, then in effect the current
goes to zero prematurely, the "lossy line" is less than 90 degrees and
the input Z has both a lower value real part and a capacitive
imaginary part.

By adding a capacitance at the open end, we in effect "give the
current someplace else to go", thus making the antenna appear to be
electrically longer. With the correct value of capacitance,
efficiency is increased because the current throughout the monopole is
increased. The feedpoint reactance is also taken to zero.

>
>Is it because the additional capacitance is being added at the end of the
>antenna?

Yes

>I know it is impossible or difficult to add inductance at the feed
>point.

No it is not impossible nor even difficult. If you take a measuring instrument and determine the value of feedpoint Z, the instrument hasn't a clue as to what the circuit is comprised of. It is a black box and if it measures 25 -j25 then adding +j25 in series with it makes it measure 25 +j0. It is as simple as that. Not complicated at all.

Hope this clears it up for you. Some hitting of a good antenna book would help some more.

Back in those days, microfarad was often written "mf" or "mF". In today's SI nomenclature, mF would be millifarads.

I don't think the problem is entirely restricted to this side of the pond. When I was in England a year and a half ago I saw that all the road signs listed distances in miles, inexplicably abbreviated simply "m", which the rest of the world uses to mean meters (or metres). I believe they also use "m" for metres, so I guess you just have to figure out what it means by context. Temperature was in Celcius, though.

In fact, the finest example of metrication of a country formerly using the English system can be found on this side of the pond. Canada. Let's take our hats off to our neighbors to the north, eh?

Adding shunt capacitance at the far end of the wire increases the series capacitance at the input end of the wire, which decreases the series capacitive reactance at the input end of the wire. So it has the same effect on the input reactance as adding an inductor, and with less loss. An additional advantage is that it increases the radiation resistance, which improves the efficiency. A third advantage is that the resulting antenna is more broadbanded than if you simply put an inductor at the input. The only downside to top loading is the relative mechanical complexity.

It's neither impossible nor difficult to add inductance at the feedpoint. You simply insert an inductor in series.

Roy Lewallen, W7EL

>very close.

>Bill

Yes as to noise, no as to heights but that depends on something else!

The term 'heights' is a relative thing, depending on the frequency that is contemplated! Remember that for radiation angle we are muchly concerned about height over ground as fraction of the wavelength for horizontally polarized antennas.

A quad can be thought about as two closely spaced yagi antennas in a stack space a quarter wave apart with the ends of the yagi's bent over and touching themselves at the voltage point!

That means on the LOW bands, such as ... sorta ... 20 ... and for sure on 40 and 80 meters, 'lower heights' can be important. I think if you will do that computer model work, you will find that a typical quad really offers little practical advantage over a yagi at the 'lower heights' on 20-40-80 meters as compared to a yagi at the TOP height of that quad wire!

But things do change for low height quads on the low bands if you do something not quite so obvious to many folks! Move the feed point on them so that the feed point is up in the middle of the VERTICAL wire portion and that they are vertically polarized! If you will do that for a 40 or 80 meter version of this, the low level quad may not be the stellar performer that it would be up at, say an installed height of 120 feet on 40! But it will be a *FAR* better performer than if you try to feed that lower element, say 8 feet off the ground in horizontal polarization!

I think you can confirm what I'm saying by computer model work if you like. As well, you will also likely learn that these antennas, down lower to the ground, do not offer much worth in expanding past the three element size, The incremental performance of them at many more elements is just not there, but is also adversely affected by the ground image when in close proximity to the ground as well. The issue is much

the same as trying to use a multi-element vertically polarized yagi down close to the ground. Practical optimization of performance simply does not come into good focus with parasitically driven elements in low-level mode like that; it has to be gotten with correctly phased power supplied to each element to really shine for you ..

In any event shifting the polarization to vertical mode will MARKEDLY improve your low angle radiation down on 40 and 80 with the elements down low to the ground!

--> Sleep well; OS/2's still awake! ;)

Make, model, condition, material, on ground or do you have to take it down, accessories, etc? All this makes a big difference in its' worth.

FWIW, I have purchased two Tri-Ex WD-51 heavy duty free standing 51 foot towers over the past five years. One was almost new condition, and came with a Ham IV rotor, control box, mast and thrust bearing. I paid $400.00 for it. The second one had some slight surface rust, and needed new cables. It came with a thrust bearing and 15 foot HD mast. It was also on the ground. I paid $200.00 for it.

Steve and the various pundits:

That stuff is made for LAN (local area network) use. I forget which particular one. Connecting computers together. Connectors are available from numerous sources, Pasternack being the most expensive. Triaxial is the commonly accepted terminology. Twinax is yet a different beast, with even more expensive connectors.

Now, pay attention, I'm only going to post this once:

The RG/ system of coaxial cable nomenclature is obsolete and unsupported. You can label any wire any RG number you want to. If you are interested in purchasing cable with specific specifications, you must use the M17/ nomenclature, as it is the only universal specification system still recognized and supported by the DOD, where the RG nomenclature came from originally, but which became so corrupt, it was dropped. All this RG/8X and "RG/59 type" and similar nonsense should have alerted you.

Now, it is likely that the size and possibly the HF loss of your cable may approximate RG58, if only the first shield is considered. Otherwise, it is larger in overall diameter, and who knows what the VHF loss might be. Depends on what dielectric they used, which isn't particularly critical for a LAN. The outer shield would be connected at both ends to the inner shield, only because you shouldn't leave a conductor floating for electrical safety reasons.

AM broadcasters also use this approach (when the insulator is cracked and no
one wants to jack up the tower to replace it in the middle of winter !)

For "Fair Condition" I would also factor in the cost of replacing hte
winch, cables and pulleys. Check those items very carefully for
wear, rust or damage.. A used tower can be more of a problem
than a bargain sometimes.

Hi Bill,

It is unlikely you could tell the difference between a good filament
and a shorted one except to apply the rated potential and see how
bright it glows. Specs of several amps at several volts would suggest
in the neighborhood of 1 Ohm, but that would be with a HOT filament, a
cold one has much less resistance. You will need a pretty good VOM to
read fractional Ohms reliably. An open here is an obvious call for
taps. Shorts (any reading less than a megOhm) between ANY other
combination of pins is also not good news.

Beyond that, there is no way to tell if the tube is good without
putting it in the actual application (or build your own tester which
amounts to the same thing).

I've use a/c fan switches before. Seemed to work just fine. They are
24 v relays. I used this on a dual band ground plane one time to
switch from 40m to 17m. MK

The top-grade flexible CATV cable is called "quad-shield" and all 4
shields (two braids and two foils) remain connected together...there
would be no way to isolate them in any case.

Bill, I tested my suspected intermittent tube by vertically mounting the tube externally on a cigar box and connecting only the filament leads to the SB-1000 transformer via 3 ft 12 AWG wires. I then built a 150 VDC , low current power source by charging up ten 15 VDC electrolytic capacitors and connecting them in series across the grid to filament.
I then monitored the 150 volts with a DVM . I gave the side of the tube a slight tap. When the tube was warm the sagging grid would briefly touch the filament and discharge the capacitors. I ordered a new tube with a graphite plate from RF Parts.

If you were serious about DXing you would tune your own receiver instead of waiting on other to spot dx for you. Better yet, tune multiple receivers on multiple bands.

If you dont know what you are contributing $$ for, dont contribute. its as simple as that. Your idea of an improvement isnt necessarily the same as others. Perhaps you now know that. Some may feel its of more value to have a cluster that wont crash or that is more real time than one that has all the "bells and whistles" you want.

Yep. I have a silver-plated paperweight labeled "3CX3000A7 Rebuilt by Econco"
that I bought as a freshly rebuilt, unused tube.

I know it was unused as there were no finger stock marks on the new silver. To
test it, I took over to a friend's place and plugged it into his Henry 8K amp
and turned it on. Uh oh, no filament current.

Yet with an ohmmeter the filament shows continuity. The heating (what little
there is) apparently disconnects the bad weld and opens the filament.

If you will look at the window for entry of the transmission line, you will
find that the transmission line goes from one wire to another wire. Those
are the two "extra" wires and they must pre-exist as numbered wires in
the wire entry section. The length of the transmission line is normally
the distance that those two wires are apart.

12/16/01

Hi All,

I would appreciate your experiences with antennas in apartments. I have been looking at some designs, and I'm sure there are many more out there.

Right now I am using about 30 feet of wire strung through the venetian blinds. It works after a fashion, but I feel I can quiet it down and increase the signal strength

The antenna is strung West to East with about 6 feet of lead from the radio to the hung part of the antenna. This is the 11th story of the building.

There is no way to ground any part of this circuit (I wish there was), except through the ground on the electricals outlet and that (at times) can be a better antenna than the antenna itself. The electrical noise is beautiful if you enjoy that sort of thing.

Nothing permitted outside the windows

Any URLs or articles that can point me in the right direction are appreciated. If you're using it, your personal observations would be helpful as well.

From what I have seen, we are getting more and more apartment dwellers, myself included. Had a 200 foot run when I owned a house. .

This will be receive only and should cover all bands from 3.5 through 30 MHz (SW Listening) Below the BC band would also help, but it's not a requirement. I don't want to fell the apartment up with wire.

If I go above 30 MHz, I have a whole new set of problems to contend with. Later!!!!

Regards.

Don

Thank you.

I'm a tool maker with my own workshop so I should be able to work
within the tolerances. Just want the fun of building my own. But to
buy may be the best option to get me up and running quickly.

I suspect if you walk up to somebody on the street in any country and
say "puff" to them, the results would be the same :-)
Seriously though, I think it is (or a least was) pretty common amongst
electronic-folk here in the US. I personally don't use the term because
I think it sounds silly...kinda like saying "73rds" to somebody in
person.

The usual dilemma...

You'll find lots of information in the 'VHF/UHF Long Yagi Workshop' on my site.

If you're interested in a crossed yagi, also check the 'Polarization Pages' in the moonbounce section - there's a long article by F/G8MBI which will tell you in detail about his experiences with constructing and evaluating them.

I recently had one in my Henry that developed a short from grid to filament.
It showed a short using a VOM. The symptoms on the amp was a negative grid
current and a small amount of plate current in standby.

I use a broomstick antenna that I found at
http://www.radiohc.org/index.html I feed it into a MFJ-971 tuner. It is
made for 80m and here in WA I have heard stations from Fallon, NV, Phoenix,
AZ, and Calgary, AB,Can on 80m. On 20m I have listened to PA and LA, plus
many stations in between. I am pleased with it

I used a 6' 1-5/16" wooden pole I got at Fred Meyers with an aluminum pie
plate for the capacatence hat. The pole is upright in a Christmas tree
stand I got at Goodwill. I wound 125' of #20 solid copper wire, tight
spaced at the top, wider spacing in the middle and large spacing at the
bottom.

It will work even without the tuner just not as well of course.

Hi Bill,

I don't know how common puff is now, but it was in A School back in the 60's when we tuned our sig gens in "motor cycles."

In contrast to other's experience, I mostly saw it expressed mfd or mmfd (in almost any mix of case, but generally with the 'd').

How many can read the mica color code? (without digging out the cheat sheet.) Yes we live in wondrous times when that convention was left behind with modern packaging and marking techniques that made it so much easier to read the value --- that is until they shrunk them to surface mount. Sometimes the march of progress is a jackboot up the .... Back in the 60's the rationale for S.I. (System International) units of measure was to bring uniformity to expression and to remove antiquated expressions (an argument that seemed to be in glaring contradiction to our migration away from cycles-per-second to Hertz).

Hi Wes,

You might want to look at the pin/wire connection. My buddy's AMP ran so hot that it desoldered these pins and wicked out to pool at the bottom of the rig. He had intermittant operation (as the wire migrated in and out of contact) that drove him nuts. I'm sure you would have already noticed something so obvious, but examination may still yield reward.

Tin the braid before you shove it into the connector (a must). If you really want to cheat, widen out those little holes with a reamer or hacksaw so that the soldering tip can fit in and gives you more surface area to solder to. Do the center pin last.

There are automatic tuners intended for single-ended antennas like
verticals, that switch reactances into and out of the antenna circuit to
match it in response to the input frequency.

Why are there no automatic tuners with balanced outputs for dipoles?
Or, if there are, who sells them?

Source record: 152632

Wires 1, 2, and 3 are the dipole. Wire 5 is a wire representing the
outside of the coax. Wire 4 is required to provide a connection point
between the transmission line and source. Wire 2 is very short to allow
connecting wire 5 near the transmission line connection point.

After opening d_DipTL.ez, open the File menu in the upper left of the
Control Center (main window). Select "Edit Current Antenna Notes". This
gives you more information about the model.

Then Open the Help menu and select Contents. In the left pane, click the
+ box to the left of "Building The Model", and locate and read the
"Using Transmission Lines" chapter. Note especially the last section
"Modeling Coaxial Cable".

Well, you could even before it became obsolete...though you might not
have been able to sell it to anyone who needed real RG-whatever. But
it does seem like they could have found a number a bit closer to what
the stuff is. At least if it says, "RG-58 type," I have an idea it's
not gonna be 'zactly what my books say RG-58/U is s'posed to be.
Triaxial RG-58A/U is about as far as I've heard things taken, though
there's probably worse.

Cheers,
Tom

John,
Actually, the antenna tuners your speaking of can be used
with coax fed dipoles too. The center conductor going to the
'pole' for the 'single-ended' antenna, the braid going to the
ground of the tuner. No reason why it shouldn't work just
fine.
'Doc

4085. Re: Links for learning how to solder.

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-17 11:16:28 UTC
From: Tom Wagner - N1MM <tfwagner@snet.net>
Message-ID: <gukT7.542$dX1.453507210@newssvr10.news.prodigy.com>
Source record: 152638

The key to soldering PL-259's is to use
an 80-100 w IRON. Soldering guns
do not have enought thermal mass to
do a good job.

I use a Weller SP-80 (80w), which I found at
a hardware store.

No tinning of the braid is required. Here are the
steps:

1. With a sharp utility knife, cut 3/4 of the way
through the cover, shield and dielectric. Take
off the shield & cover, and with a pair of
electrician's pliers remove the dielectric as
gently as possible. Don't over-twist the
center conductor.

2. Cut the cover about 5/16" from the last
cut. Don't cut all the way through, just score
it. Judge the distance by comparing to the
connector.

3. Lay the cable on a workbench. Take
the utility knife and with it perpendicular
to the cable and parallel to the table (nearly),
cut lengthwise from the score to the end
of the cable. The idea here is to come
in at an angle to avoid cutting any of the
braid.

4. Peel off the cover, exposing a nice,
sharply delineated braid.

5. PUT ON THE SCREW PORTION OF
THE PL-259!

6. Screw on the body of the PL-259. The
braid should be visible in the four holes.

7. Lightly clamp the cable in a vise.

8. Poke the corner of the iron into
one of the PL-259 holes. Wait 3-10
seconds and start adding solder. You
may need to wiggle the iron to allow
the solder to flow into the hole. Don't

add too much solder.

9. When the solder has flowed smoothly,
remove the iron and let cool. The connection
should be smooth and bright. If not, reheat
and add a little more solder.

10. Repeat for the 3 other holes.

11. Solder the tip. Sometimes it seems
better to do this twice. Once to plug
the tip, the second to finish it off nicely.

12. Cut off the excess center conductor
as flush with the tip as possible. File
if necessary.

You are done! If you don't use an 80-100
watt iron, you won't be happy.

You can use a smaller iron if you pre-heat the connector body with a hot air gun. It's cheaper than a special big iron, and useful for lots of other things too.

As being from the other side of the pond (Europe), I can also recall
these mysterious (quite frequent) capacitors from when I was a kid,
slaughtering old Valve-BC- RX's. I am not sure of origin, but I kind
of doubt they were UK. I have also seen capacitors marked with cm
(=centimetres?!?!). So, I think it must BE centimetres and metres.
It is not TOTALLY witless, normified capacitance COULD be measured
in metres, farthings (as they'd probably be using in the U.K. :-))),
light year or any other length unit.
As C = A x ephsylon-zero / D, the quota A/D having the unith length...
But I do not claim that the lenth units on capacitors really mean this.
It's just an old theory of mine. Glad if anyone can tell me if I'm
right or wrong.

Hi John,
LDG Sells an auto tuner and balun kit which will do what you want, and it
works quite well.

As others have said , use a big iron or if you must use a gun rated over 200 watts. I have soldered them for years using a 125 watt weller gun and never did like the way the job was done but they looked and worked ok. Got a bigger gun a few years back and it does a much beter job. One other thing that helps alot is to get the silver kind of connectors. If you are using the plated brass connectors , take a small file or other means and scrape the plating off down to the brass where you want the solder to go.

They would probably be almost twice as expensive as single-ended
autotuners which are already pretty expensive. Check out my web
page for a cheap notuner solution.

Because the coax may arc? Because the balun will see an impedance
far removed from its designed-for impedance?

Bliss makes balanced output tuners. They have a hand-cranked version, and a
motorized version, too, but it's damned pricey...

http://airwaterkinginc.purification.com/BlissZMatchMaster.htm

There's a couple of reviews of them on eham.net if you're interested.

Other than that, I'm not aware of any auto-balanced-output tuners being made
since the old Heathkit model that came out in the 70s. There was one for auction
on ebay yesterday. Went for over $300, and it was broken, at that.

Hi,
I've picked up in an estate. A pair of coils that are marked SH-160 and the other pair SH-80 . I assume that they are for short dipoles. I got them with no wire or documentation. I checked Alpha Delta's , Spiro, and W2AU websites , and have found no info on them. So I was wondering if anyone is familiar with them. Thanks in advance.

It probably depends on how long they have been reading schematics and
construction articles. I remember both 'puffs' and 'mikey-mikes' from
different generations of magazine articles 20 or 30 years ago, but
don't ask me which was which. I mostly read Radio-Electronics, HAM
Radio and Electronics World magazines, which should date me somewhat.
That was long before 73, Byte or Kilobaud were even a gleam in
Wayne's eye.

I selected a quad because...
5 band performance
shorter turning radius (was an issue for me).

I reccomend the remote relay feeding the 5 bands separately from 1 feed line. Don't get talked into one of the "all band" feed points.

I have not found modern quads, with fiberglass spreaders to be a weather liability.

Well, I've been told that there will be problems, because the output of
the autotuner, after it has tuned, could be at a very high impedance and
high voltage. At a high impedance/voltage level, coax might arc, and a
balun probably wouldn't work because its design impedance is about 50 to
a few hundred ohms rather than thousands of ohms.

John

The SGC range of tuners work great with open wire up to a doublet on all bands. I have been using mine in this configuration with a 20m long doublet and 12M of 3" spaced open wire for years with no problems. Take a look at the handbook on the SGC website at www.sgcworld.com to read more.

Thanks very much, Ralf. I see that it's for 100 watts, 1.8 to 30 mhz,
and is remote mounted with coax up to the remote unit. It's just what I
was thinking about, and at 660 euros, (about $500 US?) it doesn't seem
too expensive.

73 Magazine was published long before that. I subscribed to 73 back in the
early 1960s, and perhaps even in the late 1950s. I am sure of the 1960s
dates because 73 was one of the magazines I did not renew when I moved to
Canada in 1966. Are you aware that W2NSD used to be the editor of CQ
before he started 73? He's no spring chicken if I (now 66 years old) read
magazines edited by him when I was in my 20s and early 30s. Has the
technical accuracy of the stuff in his magazines improved since then?

Don--
My best indoor antenna was a horizontal loop(about 50 feet of wire). I managed to string the loop around the room using nails, thread and buttons for support. The loop was fed with 75 ohm coax to an antenna tuner. It worked reasonably well at 14 MHz and above, and I had an occasional 7 MHz contact.

At one time I used a mobile antenna inside, with a single ground wire. This did not work well, and as luck would have it, the antenna fell over one day and struck a curtain that had a few metallic threads woven in. That started a fire, which required a QRT and some wet towels.

It is called "at-will employment", and it is actually LOSING ground all over the country and has been for many years, at least a decade. There are so many exceptions to the "at-will" doctrine created by the courts, that only a fool (of a manager) would try to exercise it with any employee from a protected class. In addition, at-will employment is a state by state law, not a federal law.

In an "at-will" state, you can fire for any reason or no reason......BUT, you cannot fire for a protected class reason, as both federal and state anti-discrimination laws pre-empt the at-will termination rights of an employer. There is also a "public policy" exception to at-will termination. If the court finds you are violating established public policy (like firing someone for voting), then the "at-will" proviion no longer applies.

Protected classes:(federal) include, as far as I can recall:

Age (anyone over 40)
Race
Ethnicity
Religion
Disability
Gender

Being short, fat or gay is not federally protected. Well....if you're REALLY fat, you might qualify as disabled, but I'm not going there.

Some states have more protected classes or set the Age at 18! (Iowa is one). Some municipalities have similar "additions" to the protected class list.

"at-will" employment was not designed as a "way around" the anti-discrimination laws....because they are already a clear exception (stated in law) to the "at-will" doctrine.

Not being a lawyer, but having worked in the personnel law area for 25 years, I would advise anyone contemplating hanging their hat on "employment at will" terminations, to do a real job and terminate people only for reasons they would be comfortable putting in front of a jury....because that's where it may well end up. (after you get done picking buckshot out of your behind from the civil rights commissions and the equal opportunity commision)

If anyone thinks they can use the "at-will" doctrine to fire people for being muslim, union members or any other such balderdash, they won't be in business very long. If an employee alleges that an employer fired them "at-will" as a pretext to their protected class status, the EMPLOYER ends up having to prove that they DIDN'T fire them for that reason....it's a corporate nightmare, and it doesn't cost the complainant a penny to make a

company go through hell, proving a negative.

You can fire people for a LOT of bad (poorly justified or thought out) reasons, and you "might" get away with it in an "at-will" state. If, however, the person you fired is a member of a protected class, don't even consider it.

(and this has what to do with antennas?) I don't have a clue, but couldn't let this misinformation go without public response, lest someone should lose the ham radio budget by doing something incredibly stupid. (not to mention, wrong)

Source record: 152664

Just installed a 2 element, dual polarity beam (Avanti PDL-II). It is the first time I have ever played around with a dual polarity beam, coming off having built my own 4 element horizontally polarized quad. After listening to DX signals and playing around, I found (as expected), the best signal strength was obtained by varying the polarity switch, about 33% of the time horizontal was better, 33% of the time it made no difference and 33% of the time vertical was better. Some times received signal polarity was constant and sometimes it varied second to second. Having the ability to maximize TX/RX signal strength the other 66% of the time, to me, is like adding more gain compared to another antenna with the "wrong" polarization.

Anyway, this made me wonder, is it really more of an advantage for a contester to put a large monoband beam (ex. 7 element yagi), oriented in a fixed polarity? Over the course of an average contact, to me, it seems polarization diversity outweighs pure forward gain. In the worst case, a signal could be down 20dB - even a 7 element receiving a weak signal down 20dB seems like a *large* disadvantage. I will admit, the worst case (90 degree difference) is always stated in text books as 20dB, but I think one rarely finds this much difference on a "DX" signal, as polarization isn't "pure". Also, I have seen the case where offending signals can be reduced by switching polarity - making it easier to have a CW contact.

I see many advantages to a dual polarity setup, but this just doesn't seem popular. Any good insight (other than "most man made noises are vertically polarized")? Having never sat down at a station with a long boom 7 element Yagi, I can't really say how my theories stack up in the real world.

Scott.

Your Friend Bill <"Remove The NO In The Reply Address"@coqui.net> wrote:
: hasan schiers wrote:

: So which is a "member of a protected class" in the case of say,
: religion?

Hypothetical example:
Man of Mid-Eastern descent and origin moves to the US, becomes
a US citizen, is working for a private employer, and continues
to be a practicing Muslim. His supervisor gets irritated because
his employee takes time off for his prayers, observes Ramadan,
or is not clean-shaven. Supervisor then decides to get rid of
that employee and focuses on minor attendance problems and fires
him for being a few minutes late on some days when traffic was
bad, for being out sick for three days a month ago, and for
being otherwise "undependable".

The employee complains, the local or state authorities come in,
discover that other employees who weren't fired had comparable
attendance records, and that the Muslim was well within the
norm for attendance. They also discover that the supervisor
was concentrating only on the Muslim, and not acting on the
attendance records of other employees.

The employer is in _Deep_ trouble.

The Muslim might also complain that the boss was discriminating
against him because of his national origin. If _anyone_ in the
management structore there _ever_ mouthed off to the Muslim
about where he came from, then the Muslim may well be able to
make charges of a Civil Rights violation stick.

And since Civil Rights violations are a Federal matter, the
Muslim could take the employer to Federal court without even
getting the state or local authorities involved. Any trouble
he might have thought he was in with the state and local
folks would be totally negligible when compared to what the
Feds can do.

Or at least that's what I was taught in my management law class.

Mutatis mutandis, you can talk about a Sikh who wears a turban
and kirpan, or a Catholic who comes in with ashes on his/her
forehead on Ash Wednesday, etc. Additional examples are left as
an exercise to the student.

Hi Scott,
I was with Avanti when this antenna was developed and had a chance to do a lot of testing with it- a 10M a 6M model. Single hop Es was amazing- deep QSB could be many times eliminated entirely by switching polarity. Later I built a 4 element yagi with both H and V elements for 6M w/ same results. Polarity diversity (as well as space diversity) are well known but little used today on HF.

Source record: 152572

Is a double bazooka antenna inherently balanced or unbalanced at the feedpoint? It seems to me that the shorted coaxial stubs would probably make it unbalanced and thus no balun should be needed for coaxial transmission line. Is this correct?

International Antenna Corp www.iacantennas.com who makes them commercially claims that no balun or choke is required...

Seems reasonable that twinlead would be the worst in this regard, and that open conductors with glass rod spacers would be the best, and windowed plastic would be somewhere inbetween.

It also matters what's in the water. In hawaii, we had a constant salt-spray environment, so damp twinlead would be damp with saltwater. Here in indiana, rain plus dust equals somewhat less conductivity, and I'd expect somewhat less of an effect, on the same type of line.

I use LDF4-50 outside, which dosen't care until you start filling up the line itself with water.
:)

I would. Not so much because it might pull out, but waving in the breeze may tend to damage the braid at the back of the connector and will also cause the connector to loosen over time. Just form a little loop and use ty-wraps or something to hold it in place.

It's almost certainly true that salt water would have more of an effect
than pure water. But a lot of people don't realize that even pure water,
which has low DC conductivity, is very lossy at HF.

The effect that water will have depends on how much water you've got in
the region of strong electric field between the conductors. And that in
turn depends pretty much on how much dielectric there is for it to sit
on.

I swithed from a Hy-gain TH6DXX (a good Yagi,not one of the shrunken up ones) to a Lightning bolt 2 element 5 band quad.I don't believe the quad is better suited to lower heights,nor do I believe there is a significant difference in the noise,Yagis are not noisy.

> up to the wind and ice just fine.

Here in Montana I live on a windy hill and it hasn't been a problem.

The advantages to a quad over a Yagi in my opinion are:
1) Low price (2 el. 5 bands for $300 or so).
2) Light weight.
3) Little wind load.
4) MUCH greater bandwidth.Not even a concern if you intend to stay within the ham bands.
5) Visual impact,while ugly up close just like any antenna the wires "disappear" from a little ways off.The elements on my Yagi could be seen from over a mile away.
6) How many parts/pieces,mechanical/electrical connections would you rather have in your antenna system?

The double bazooka is a dipole antenna and thus is a balanced antenna.

It is good engineering practice to used a choke on *any* antenna that
you are feeding with coax. Regardless if it is balance or unbalanced.

Actually, you could have feed a quad with a single feedpoint so it would have equal H and V polarization. If it's a "square" element (with horizontal and vertical sides), you'd get this by feeding it at a corner. If it's a "diamond" element (with corners at top and bottom), feed it in the middle of a side. What you'd have is linear polarization that's tilted 45 degrees from horizontal or vertical, which contains equal amounts of H and V polarization.

I have one - it's a TenTec Model 253 - tunes Coax-fed or balanced line fed antennas - switchable from the front panel. Yes, it's an automatic KW antenna coupler. TenTec doesn't make them anymore, since they were quite expensive new, but they do pop up used sometimes, usually around $600-700. I'm not using the balanced output on it right now, but I am using it on several coax-fed antennas with my Alpha 87A amplifier at 1500W output with no problems.

Hi John,

actually it's perhaps not exactly what you want, since it is not fully automatic. The tuner consists of two boxes, one in the shack and the other at the antenna, connected by a multiwire cable. You have to search for the best match on your own by turning the knobs on the box in your shack and then put the settings into a memory. You do this for all bands and the next time you will have to set the memory switch into the right position (like a bandswitch).
The tuner itself uese a balun in the input and then a symmetric pi network switched in the same manner as the Smartuner or Icom AH 4 or whatever.

I think being close to 600 US dollars the price seems o.k. to me.

I've done it that way on my low wire quads on 40 with the bottom square element run about 6-8 feet off the ground.

Again, in this instance, things came alive much better fed pure vertically from a side element.

But here, there was a practical issue to this which was more important as to the choice of feed polarity! It was well grounded logic! (chuckle)

I think as one goes forward with this, in practice, one can learn something else fascinating about all this! You may get enough wire and metal up on 40 or 80 meters and enough receivers and a scope to really begin to play with this! Then you can watch TWO antennas and receiving setups at the same time! You will find that far away signals on the low bands will actually arrive first on one polarization stronger, then on the other one, over short lengths of time, all from the same originating site!

I used to watch DX signals from my low wire 3 element 40 meter quad at the same time I watched them on my vertical array! You could actually see some variations in the amplitude, which I assumed were polarization specific, at any given instant in time! Over short periods of time, the signal would favor first the quad, then the vertical, and so on! The effect wasn't massive, only a couple DB or so, but it was there.

The conclusion I reached, was the the signal polarization is being altered in the skip process on low band work.

Thus think I've learned that where skip, especially multiple hop paths is concerned, getting as much of the radiation into the proper takeoff angle range is far more important than the fact that the originating antenna is polarized either horizonatally, or vertically!

You can .. chuckle, perhaps, improve your effectiveness on low band, by feeding a vertical array on 40, say, with a KW at the same time you feed

a horizontal array also with a KW from a split amp source! That way you get to contemplate what goes around comes around at the far end of the path! And maybe even win! But you'll possibly have to argue about what goes around comes around with the regulatory guys as well! They may not appreciate your amateurish engine ooity in playing copyKat with the FM broadcast industry in the basso profundo frequency ranges!

So I'll leave it to the more affluent 'mungst us, to prove, on the average, how much less than 3 DB you'd see at such a caper, over many days of tests. But it should be a fun project! After all, the folks that grade and score the DX contests tell us that, over the long haul, equal operators at two competing stations, even one DB more makes a difference in the final standings!

--> Sleep well; OS/2's still awake! ;)

Hi all:

It seems to me that just putting some twists in the feedline as it comes away from the antenna would help minimize the problem by encouraging the water to run off. Gravity works even on small water drops. It wouldn't eliminate the problem but I think it would minimize it. Besides it would help make sure the local noise was induced equally into both wires of the feedline. It wouldn't look as pretty though.

> ...

An interesting question.

Roy gave the correct answer, in that if the quad was 'tilted' (that is, fed at a corner) it would have equal amounts of horizontal and vertical.

All of this is assuming a full wavelength circumference, however. It is theoretically possible to have a loop that is something other than a wavelength around.

I saw an article once on a microstrip patch antenna that was nothing but a square of copper on the PC board. Actually, it was not exactly square. One side was slightly longer than 1/2 wave, the other slightly shorter. When fed at a corner it would radiate circular polarized. More recently I saw an article on a turnstile antenna that had different inductors in each element. When the two dipoles where fed in phase it would radiate circular polarized.

What I am wondering is if the same thing could be done with a quad that is 1/2 wavelength +/- on a side (or loaded somehow). A bit big on 20 mtr, but do-able on VHF.

Roy, you ever heard of this?

Jim

4154. G5RV 10/15 Meter problem

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-18 17:05:27 UTC
From: rcuffee@hotmail.com
Message-ID: <df27559b.0112180905.407937a9@posting.google.com>
Source record: 152607

I have a G5RV (10-40M version) installed in an inverted-vee
configuration. It is installed at 35 feet and the ends of the antenna
are 15 feet off the ground. I am having problems on 10 and 15 meters.
On 15 meters, I hear VERY little DX and stateside QSOs. On 10 meters,
I get major RF in the shack when I transmit, and the antenna works
like a cloud warmer on this band. I can hear DX on SSB, but I usually
can't work them. I normally us 100 watts with a TS-2000, and the coax
is about 60 feet long. Any suggestions?

Thanks,
RC

4155. Butternut HF6V 10/15 m performance

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-18 17:08:35 UTC
From: rcuffee@hotmail.com
Message-ID: <df27559b.0112180908.49bfdf0d@posting.google.com>
Source record: 152608

I currently use a G5RV (10-40M version) and I am thinking about
getting a HF6V vertical because my G5RV is a cloud warmer on 10 meter
and does not hear well on 15m. How is the performance of the HF6V on
10/15 meters when is ground mounted?

Thanks,

RC

When fed that way you get triangular polorization. And if the quad is made of round elements you get circular polorization, the left and right hand is determined by which way the center of the coax is hooked to.. :-)

4160. Multiband vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-18 20:14:27 UTC
From: marieandpaul <marieandpaul@hotmail.com>
Message-ID: <9vo833$mt7$1@knossos.btinternet.com>
Source record: 152613

Hello,

I want to construct a multiband traped vertical but need info on the traps. What formers , wire, turns et etc. I have looked at articles in the ARRL books and have loads of theory but no practical information. Can anyone help please. (marieandpaul@hotmail.com)

4161. Random vertical for 160 meters?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-18 22:37:28 UTC
From: Webster Williams <kr4wm@sc.rr.com>
Message-ID: <MPG.16898f636dae98d989815@news-server.sc.rr.com>
Source record: 152614

Question: I have some random lengths of aluminum tubing
that I would like to fasten together to form a 160 meter
vertical. I would like to place it atop my chain link
fence that surrounds my yard. I attempted to put up about
30+ feet to see where it would resonate without any sort
of matching network, and using my MFJ analyzer, it does
not resonate ANYWHERE! I'm fairly certain that the reason
is because of the random nature of the chain link fence
not being a 1/4 wave reflection of the antenna.

Before anyone tells me that 30 feet of tubing will not
naturally resonate on 160 meters, I know that before you
reply. But I assumed that it would resonate SOMEWHERE on
SOME UNKNOWN FREQUENCY, even with an unmeasured counterpoise.
It won't. I thought it would resonate somewhere above 40m?

Any good ideas on how to match a combination like this?
I will eventually get around to installing a loading coil
midway or higher up the antenna. I guess the matching is
going to be the key to getting everything to work.

I tried shunt feeding it (again with a random length coil
and tapping along it) but never found a "sweet spot" on
the coil that the mess would resonate anywhere. Should I
have tried a capacitor instead? Or a combination?

I will likely play with tuned radials on my next day off
from work. I'll probably have to suspend them above the
chain link fence somehow. (?)

Thanks in advance for any ideas!

Source record: 152616

Web,
I think I would agree with you about the chain-link
fence being the 'problem'. Not because of it's random
length, but because of the terrible, or nonexistant
contact between all the various 'parts' of the fence, and
also the almost nonexistant contact to ground through
the concrete used to hold the posts. Fences like this
usually make very poor ground systems, aside from being
the cause of 'humongus' RFI problems.
The 30 foot vertical should be resonant around 8 Mhz.
'Trim' it slightly, add a good ground system, and it should
do well on 40 meters and maybe 15-20 meters. Add a fairly
good sized loading coil and you should be able to make it
work about anywhere. The first thing to do is forget the
fence and 'do' a conventional ground system.

Source record: 152618

Webster:

I hesitate to ask this, and don't be insulted, but did you insulate the 30 foot vertical from the chain link fence so you could feed it at its base?

The reason I ask is that if you did, you should have found a resonance near the 40 meter band. The chain link fence is an unpredictable part of the resonant antenna system, but it would probably show a number of resonances in other parts of the HF spectrum, in addition to the strong resonance near 40 meters. I used to use a ground mounted 30 foot mast on 40, with no matching of any kind. Coax shield to a ground rod and center conductor to the mast; which was insulated from ground at its base. Worked well enough for many contacts with JA's, and an occasional VK and ZL in the mornings on CW. I later added some radials but didn't notice much change in the performance.

30 feet is a little short for 160, but people are running 160 mobile with 8 foot whips, so you will have an advantage over them. A good ground radial system will help, but you can proceed in steps, adding improvements as you go along.

Go with the J-Pole. Much better antenna then a 1/4 wave, no ground
radials etc.

I made on out of aluminum wire from RS and it works great in my
apartment. Even sitting next to the wall didn't "detune" it. If you make
one out of copper you could use it horizontally for SSB if you were so
inclined. (but remember that an antenna with more gain would be better
for SSB.

The noisy part comes into effect when it's snowing or drizzling rain during low humidity. The static from snow on the Yagi will obliterate the bands while the quad will never even register it.

> The advantages to a quad over a Yagi in my opinion are:
> 1) Low price (2 el. 5 bands for $300 or so).

Limited to the spider quad, more or less.

> 2) Light weight.

Spider quad.

> 3) Little wind load.

Yes, but only for the spider (2 element) quad. Introduce a boom for the 3-4 element support and you're increasing the load exponentially.

> 4) MUCH greater bandwidth.Not even a concern if you intend to stay within
> the ham bands.

I don't think this is true. A well designed (not shortened) Yagi should have a wider bandwidth than a similar performance quad - after all, it has a larger diameter elements (tubing - wire).

> 5) Visual impact,while ugly up close just like any antenna the wires
> "disappear" from a little ways off.The elements on my Yagi could be seen
> from over a mile away.
> 6) How many parts/pieces,mechanical/electrical connections would you rather
> have in your antenna system?

Again - spider quad. The two element quad is a wonderful antenna for the money spent. Definitely a better choice than a 3-4 element triband Yagi. However, move into the 3-4 element quad territory and all of the above goes out the window. Not to mention the wire breaks, painting of the spreaders (yes, even the UV-resistant types), etc.

Wait a darn minute Roy! Don't discount your very own USofA federal
government. These folks have metricized one of our very own Interstate
highways. I-19 runs from Tucson to the Mexico border (or is it the
other way around?).

Distances and speed limits are in Kilometers and Kilometers per hour.
I believe that this was done so that the illegal aliens and drug
runners would feel more comfortable during their journey into the
states.

And don't forget, speedometers on cars now have dual scales. This is
handy for the guys driving the cars stolen in the car theft captial of
the country, ---yep, Tucson, AZ---down I-19 to Mexico. They have
metric speedometers and speed limit signs so they have less chance of
getting caught speeding.

Sterling examples of how the adoption of internationally agreed upon
units can improve the flow of goods and services between the countries
of the world.

Oh and another thing, the US Customs service has gone metric too.
They give the weight of confiscated drugs in Kilograms.

Of course if the speeding thieves do happen to get caught there is new
hope for them. A local judge just asked the DA to start including
non-English speaking people in jury pools. Gotta be fair and give
them an OJ-like jury of their "peers".

Is this a great country or what?

RADIO HABANA CUBA
DXERS UNLIMITED

MID-WEEK EDITION
TUESDAY, DECEMBER 18, 2001

By Arnie Coro CO2KK

Send your comments, questions and ideas to: arnie@radiohc.org

Hi, amigos! With less than 2 weeks left of the year 2001, old man Sol, our nearest star, continues to provide radio hobby enthusiasts with very nice propagation conditions.... Early morning Tuesday local time in Havana, I was able to pick up some interesting signals that indicated a very fast rise of the daytime maximum useable frequency curve.... and although solar activity is expected now to move down for the next few days, the fact is that there is so much ionization at the higher levels of the ionosphere that free electrons are really plentiful, even after the Sun sets.... Solar flux still above the 200 mark, and the effective sunspot number has now moved down to around 160, still an impressive figure by all standards...

Item two: I have just updated my list of all the ways that you and I may enjoy our wonderful hobby!!! And it has grown to 63 different and clearly identifiable ways of having a nice time with our hobby, from monitoring natural radio signals on the extremely low frequencies of ELF to playing with LASER BEAM communications in order to add points to your station when participating in a VHF-UHF-SHF amateur radio contest.... And don't forget such nice ways of enjoying the hobby as antique radio restoration, radio kit-building, computer-aided design of antenna systems, building amateur radio equipment from original designs and some very interesting aspects of the radio hobby like doing intruders watch on the amateur radio bands to help keep the ham bands clear of illegal users !!!

Yes my friends, the list now adds up to 63 different ways you and I may enjoy the hobby....radio has the unique feature that it is a never-boring hobby .... with some aspects of it costing next to nothing, like the way many of us seem to have started here... SHORT WAVE LISTENING, the flagship of all radio hobbies!!!!

Item three: You have questions and Arnie answers them section of Dxers Unlimited will reply today to a question sent by several listeners in relation to the so-called coaxial cable antenna, a very

easy to make dipole that requires just a length of coaxial cable and one antenna connector, plus a small length of PVC insulating electrical tape and a small amount of silicone weather sealant, and as always at the end of the show, I'll provide you the most up to date HF propagation update and forecast which, even when heard during our late-late show at just after 0530 UTCm is never more than 12 hours old....

Stay tuned right on this same short wave frequency or if you are listening to me on the world wide web streaming audio, keep your computer connected to Radio Havana Cuba... Margarita Delgado is my sound engineer and producer , I am Arnie Coro, radio amateur CO2KK, back with you in a few seconds...

This is the mid-week edition of Dxers Unlimited, you can always reach me via e-mail by sending your message to arnie@radiohc.org and I will reply to you directly with an answer to your radio hobby-related questions as soon as I see your message displayed on my computer screen....

Now here is item three, our popular YOU have questions and Arnie answers them section of the show.... Today, I will be answering a question sent in by listeners in Cuba, Canada, the United States of America and several European nations, plus Australia... The question has to do with a very simple way of making a low-cost yet effective dipole antenna, that has proven to be very useful for portable work in the frequency range from 10 meters all the way up to the 2 meters amateur radio bands, and all frequencies in between.

This coaxial cable dipole, can also be made for lower frequencies, but it is a bit more troublesome to do the tricky operation of pushing the coaxial cable braid back over the outer jacket of the cable for a length of more than about 2.5 meters or eight feet required for the 10 meter band version.

The "Coaxial cable push back dipole," as it is known among radio amateurs, is an excellent emergency antenna for the 10, 6 and 2 meter bands, and ranks among the lowest-cost skywires that the radio hobbyist may build and install, as it only requires enough coaxial cable and an antenna male connector.... The coaxial cable push back dipole is one of my favorite portable antennas for the 2 meter band handie talkie when travelling, as it has the advantage over the 300 ohm TV twinlead J pole, that it is smaller in length and does not require any soldering at all... something that has helped me to build these antennas even right in the middle of a communications emergency with the help of my faithful pocket knife, if a length of coaxial cable with a connector at one end was available from a broken antenna... The only thing needed is that one end of your coaxial cable will have an appropriate type of antenna connector for the radio that you are using soldered to it.... Now, ready to copy, ready??? Here is how to make a coaxial cable push back dipole following these easy step-by-step instructions:

First calculate the length of your dipole antenna for the center of the frequency band you want to operate your radios on... Here is the formula: Divide the number 143 by the frequency in megaHertz, and your result will come out in meters... For example, let's make a coaxial cable push back dipole for the 2 meter amateur band.... Center frequency: 146 megaHertz.... so -- very easy -- divide 143 by 146 and you will find out that the overall length of the dipole, of course, your result will be less than one meter in length, exactly 979 millimeters, or in round numbers 98 centimeters.

Now, step two: Very carefully remove the outer plastic jacket of the coaxial cable for a length about one and a half meters, to make things easier for the next step. That is, strip the cable of its outer jacket for roughly one and a half meters and then proceed to fold back the coaxial cable shield or braid over the cable's plastic insulation, in a way similar to what you do when you are removing your stockings.... The braid will then leave a length of the center of the coaxial cable exposed to form the other half of the dipole antenna....

Step three is a very easy one: Just trim the braid that is over the coaxial cable's outer jacket so that it will be 49 centimeters long... And also cut the center conductor to slightly more than 50 centimeters, so that you can trim it later for minimum standing wave radio in case you want to transmit with this antenna...

Step 4 is also very simple: Find a length of PVC plumbers pipe of about 100 millimeters or 4 inches long, and just wind as many turns of the coaxial cable as will fit, starting from the point where the shield or braid ends. This is the coaxial choke balun, essential for the proper operation of this type of antenna....

As you may realize, this is just another way of building a half wave dipole antenna, so its gain, compared to a standard half wave dipole will be zero db d, or zero decibels over a dipole, as this is the reference antenna for practical radio work....

By the way, you must install the antenna according to the polarization used by the stations you want to listen or talk to, so in the case of the two meter amateur band FM, the coaxial dipole must be installed vertically, as by convention, and to facilitate communications with mobile and hand held stations using vertical antennas, the 2 meter FM amateur sub band stations all use vertical polarization.

Of course that you can make a coaxial cable push-back dipole in just a few minutes for any particular frequency in the range of from about 25 to 250 megaHertz, by applying the formula, and proceeding to first remove the outer plastic jacket for enough length, pushing back the shield or braid over the cable's plastic jacket, and trimming the length of the center conductor and the exposed braid to the appropriate length to make the dipole resonate. Don't forget that the coa_ial cable choke is essential for the proper operation of this

antenna, and here I must add that the choke for the lower frequencies in the range from 25 to 50 megaHertz must be wound on a length of PVC pipe of no less than 3 inches in diameter, that is 75 millimeters, winding at least 8 turns. In the range from 50 to 100 megaHertz reduce the diameter of the pipe to 2 inches, that is 50 millimeters , and as mentioned previously for the antennas in the range from 100 to 250 megaHertz, the coaxial choke diameter must be one inch or 25 millimeters.

I have done some experiments regarding the number of turns required for optimum operation of the antenna, and it is between 6 and 8 turns... Please notice that this coaxial choke is just the same cable wound over the PVC pipe "coil form" to effectively isolate the antenna from the feedline.

By tying a nylon fishing line to the end of the exposed center conductor you can install the coaxial cable push-back dipole vertically at any location, for example, it may hang from a tree branch, or supported by a plastic or wooden mast...

If you want to use the antenna, as I do here, as part of your permanent receiving or receiving and transmitting station, then carefully seal the place where the coaxial cable shield or braid separates from the center conductor by winding several layers of plastic insulating tape, and then sealing with silicone compound....

Many Cuban radio amateurs use this antenna for 2 meters FM by placing the dipole inside a length of PVC pipe for additional weather protection, but they soon found add that the presence of the dielectric so near to the antenna changed its operating frequency, so the length had to be trimmed experimentallly for minimum standing wave ratio...

Si amigos, yes my friends, oui mes amis, one of the easiest to make and lower cost antennas -- the coaxial cable push back dipole is an excellent performer, and all it takes to make one is a length of coaxial cable, an antenna connector of the type used by your rig and some plastic PVC insulating tape and a bit of silicone sealing compound for the portable version of the antenna.

An antenna for permanent, fixed, station use will be better protected if placed inside a length of PVC plumbers pipe of about 25 to 50 millimeters diameter, but again, you must carefully trim the length of the center conductor half of the dipole and of the braid for minimum standing wave ratio!!!

Any doubts, any doubts on the how to make your own coaxial cable push back the braid dipole? Then just send me an e-mail and maybe I can send you a nice .jpg picture of yours truly and the most recently built antenna!!! Send mail to arnie@radiohc.org or VIA AIR MAIL, a postcard is fine, to Arnie Coro, Radio Havana Cuba, Havana, Cuba.

And now as always at the end of the show, here is Arnie Coro's HF plus 6 meters propagation update and forecast: Solar activity moving down now, but still high enough to support very high daytime maximum useable frequencies, amigos!!! There is still one solar active region with the complex magnetic configuration required to produce solar flares. Running typical HF propagation forecasting software is not that difficult at all, and at least one of the most recent ones is absolutely freeware and works very well... it is W6EL's brainchild, and Sheldon C. Shallon, radio amateur W6EL, who owns the copyright, but kindly has made the program available free, in the public domain...

Well a test run of the W6EL's HF propagation software that I did just before finishing to type this script showed that the maximum useable frequency from Havana, Cuba to Buenos Aires, Argentina stays above 30 megaHertz from 13.30 UTC to 22.30 UTC, reaching a peak of 38 megaHertz at 19 hours UTC, so you see what I mean, the second peak of solar cycle 23 is doing a very good job to push those daytime maximum useable frequencies way up... Enjoy them amigos, and don't forget to try our new streaming audio from www.radiohc.cu!

4178. shortening a dipole to resonance

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-19 12:06:05 UTC
From: Jerry <jerryaa@prodigy.net>
Message-ID: <No%T7.490$Zh7.61700234@newssvr16.news.prodigy.com>
Source record: 152531

I just received an Autek Antenna Analyzer and was finally able to tune dipole to resonance. I found that folding back insulated wire seems to shorten the antenna the same way as if you were using bare wire. Also, apparently using insulated wire increases the electrical length of the dipole. I had used the 468/fmhz formula. It looks like at 17m, insulated wire increases electrical length about 3% over bare wire. (#16 stranded insulated)

Thanks to all those who gave their input.

> Ah! You don't have "triaxial" cable. You have double shielded RG-58.

How do you draw that conclusion? If there is another layer of dielectric between the shields, it is triaxial by definition. But Steve never said which way it is. My experience with that type of LAN cable is that they are typically triaxial, and typically mislabeled by some perversion of the old, now obsolete nomenclature. Double shielded RG-58/U is RG-223/U, or RG-55/U if your stocks are as old as mine. And, if it were double shielded, it wouldn't matter whether the outer is overtly connected to the inner at the connectors, as it is in continuous intimate contact with the inner throughout the length of the cable by construction anyway.

Normally the turnstile elements are fed 90 out of phase to have
circular polarization. Real popular for sat work. Using inductors
would be a strange way to go about it. Most use coax lines. Normally
feeding in phase will give a dipole like pattern with slightly less
gain.
>
> What I am wondering is if the same thing could be done with a quad

> 20 mtr, but do-able on VHF.

Crossed full wave loops are commonly run as eggbeaters. You can use
the same phasing schemes with those. 90 degrees lag between elements
will give an omni pattern. I'm not sure about the quality of circular
polarization though on an eggbeater. It may work as they also use
those for sat use in some cases. MK

Hi Zoran,

Ummm....

Do you use the light constant of 2.2*10ï¿½ï¿½ Furlongs per Fortnight?
;-)

Suppose we called it the Brlecic(or Clark, but I already have a cell
named after me). That would work between us, and perhaps the other
fellow reading this, but I would offer that it leaves 200,000,000,000
others out in the dark that could already cope with meters-per-second
(or miles-per-hour for that matter).

Hi all,
in the italian amateur radio newsgroup there's lot of discussion about
the maybe famous EH antenna. Nobody though seems to have really
studied the theory behind this antenna (or just explain what's the
pitfall the author fell in, if any). Beeing a telecommunication engineer
I'd like to understand better how this antenna is really working
before concluding that it just doesn't work. Is there anywhere a good
description of the *real* theory behind this antenna or a real test
conducted in scientific manner?
Thanks.

Let's try this again, the post above is too glib and not very
responsive (and it's a slow day here).

The *real* theory is that the structure being passed off as the
antenna is actually the top load of the **real** antenna. Note how
the proponents all make the claim that theirs is a short antenna, and
they then undercut this logic by putting it on the roof, or up a
tower!

A top load? The proponents would undoubtedly blow a gasket at this,
and yet when the proof is before them (decoupling the drive line from
the feed point) they invert logic such that they exclaim power would
be lost to the choke so you don't need the choke.

The feed line is radiating and making up for that lost height they
claim is not required (just before they hoist it a few more meters);
they are simply raising an extremely ugly top hat higher up the

radiator.

Well, the SI only standardized measurement units all over the world, and yes, in the process some of them changed, but the change from cps to Hertz was fairly transparent, i.e. nothing really changed except for the unit name. Compare that to where the US is today with respect to the rest of the world: I think you'll agree that we're stubborn enough to never accept "this metric stuff" and so the yards, the pounds, the quarts, the ounces, the foot-pounds-per-square-inches, the Fahrenheits and similar English nonsense will linger on forever instead of being replaced with the internationally accepted standards (based on the ten factor, btw - quickly, how many inches in a mile and how many ounces in the gallon?).

My point is the following: once the internationally recognized body with the clear authority to handle measurements changes things, it is every nation's responsibility to conform to the changes. Not only because they ratified the agreements, but because the changes make things uniform, standard and subsequently easier.

Therefore, if we were the SI and we called it Brlecic, all the nations would have agreed to that change and all would have to implement it: there would be no "200 billion others out in the dark".

Now, having lived in purely metric (9A), semi-metric (VE) and "standard" (W) countries, I can only offer you my take on the situation and it is that hanging on for dear life on this silly British nonsense (that even the British discarded) is ridiculous. But that's another story...

Triaxial cable, by definition, has conductors on three axes. Shielded cable with two internal conductors fits this definition. The conductors in a double shielded coax with a single center conductor are all concentric, i.e., share a single common axis. So it's not triaxial cable "by definition".

4193. Re: any info about EH?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-19 22:13:57 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C211125.2C313160@eznec.com>
Source record: 152546

On the contrary, there's been a lot of study of the theory behind this antenna.

The EH is a modification of the "Cross Field" antenna (CFA), which has been around for more than a decade now. Quite a number of papers have been published in professional journals discussing this antenna, one notable author being Dr. John Belrose (VE2CV). All that I'm aware of, with the exception of ones written by the antenna's "inventors", conclude that the antenna works no better than a conventional monopole of the same height. In the September 2001 issue of the IEEE Transactions on Broadcasting, there's a nice tutorial on short vertcal antennas ("Short Medium Frequency AM Antennas") in which the author, Valentin Trainotti, explains the operation of the CFA and presents measured results from a scale model CFA as well as from conventional monopoles. It's hard to do better than his summary:

(Note: The quotation below is just as it was published. The article apparently wasn't proofread by someone who speaks English as a native language.)

-- begin quote --

This antennas was attracting the attention specially due to scarce information about its behavior and specially due the high gain claiming by its "inventors." This antenna is nothing new and its behavior is similar to a short monopole of the same height. It has a short cylindrical monopole structure as a radiating system, called the "E plate," and a metallic plate under it and parallel to the ground plane, called the "D Plate". Lately in order to increase its radiation performance and facilitate its tuning, a top load was added. Monopole height is not important but if its height is too low, radiation efficiency deteriorates because of its very low radiation resistance as it was seen in the short monopole case. The D plate size is not really important because it not increases the radiation power of this array and its effect is to modify the very near field in the antenna vicinity trying to obtain E and H fields in phase in the surrounding space. The radiated field at several wavelength is similar with or without it. It complicates the antenna feeding system because its inventors connect two generators at the antenna system. One between the monopole (E plate) and the metallic ground plate and one between the D plate and metallic ground plane and 90 degrees phase difference between them. Because antenna gain does not increase with this complicated tuning system, the best way is to eliminate the D plate and using only one generator and tuning system, increasing at the same time the antenna efficiency because any additional loss in these extremely low radiating resistance

systems is highly beneficial. Of course if this is done, the "invention" disappear and a standard cylindrical short monopole is obtained. Directivity of this antenna is similar to a short monopole of the same height regardless of the kind of feeding, in phase or 90 degrees phase difference between both plates. . .

-- end quote --

The EH antenna is essentially the same thing but with a different feed system. The EH feed system depends on the phase of a current being shifted 90 degrees by passing through a series inductor. That this is impossible can be easily confirmed with a simple measurement or by referring to elementary circuit theory that's been widely and successfully used for over a hundred years.

Let me rephrase that slightly, Roy. "If it has a layer of dielectric between the shields, it is triaxial by definition of all the cable and connector manufacturers I deal with." The "tri" in triaxial apparently refers to the total number of independent conductors, and axial indicates a common axis. The cable you are describing is called twinax by the same group of manufacturers. I didn't claim any of them speak correct American English. I don't have a MIL-C-17 spec. set handy at the moment, but I believe that definition is spelled out there in there with typical DOD bureaucratic wording. I just happened to be in the T section of my catalog file and took a quick look at Trompeter and Times, and reconfirmed that both use that terminology. I do not claim to have originated it, but I have been using it for at least 30 years, as the Endevco accelerometers we used to measure vibration on oil rigs in the 60s used triaxial cable, to isolate the low, low level signals from ground loops in the outer shield, and Endevco called it triax back then.

Francesco:
Richard Clark gives you the summary of this debacle, but to answer your specific questions, yes, there have been several presentations of the inventors versions of the theory. Start with Wireless World (UK) in about 1986. The inventors wrote several articles with their initial understanding of the theory, and design details. Do a Google groups search of this newsgroup for the last 3 years using the EH keyword and you should find all those articles were referenced here at one time or another.

No, there has never been a real test conducted in a scientific manner. Some element of a true scientific test is always violated in all the show efforts.

But that "bit of gain" is up. For a ground plane VHF antenna, you
don't want your gain to be up. What you need is a multi-element
phased vertical, not a 3/4WL vertical.

4201. Re: Butternut HF6V 10/15 m performance

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-19 23:05:44 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <3c211e93_2@news1.prserv.net>
Source record: 152551

I have a ground-mounted HF6V and it works very well on 10m. It has never worked quite as well on 15m. I have 12 buried radials ranging from 65 feet to about 25 feet.

Overall, I have been quite happy with it --- but you must understand the compromises and limitations of a multiband ground-mounted vertical installed not too far from a house and with a limited number of radials. I sometimes switch between it and a low (20') dipole (cut for 30m, but used on 30-10 meters) to catch polarization changes. Sometimes the vertical is better, sometimes the dipole is better.

I have never used a G5RV. However, 10m has been so good on some days this last year that almost anything should work well. Is it possible that you have bad connections or possibly a feed line that is exactly the wrong length? Or a rig problem?

The G5RV is NOT an all-HF-band antenna. It only works well on 5 of the
8 HF bands. Borry an MFJ-259 and see for yourself. Also when you install
a G5RV as an Inverted-V instead of horizontal, you change the characteristics.
Download the free demo version of EZNEC from EZNEC.COM and see for yourself.

How do you know it's a "cloud warmer" on 10m? If its 56 feet long with
about a 14 foot matching section, it should be a resonant 3/4WL on 10m
with a pretty good cloverleaf pattern. Are you running it Inv-V?

You're absolutely correct. A quick web search confirmed that "triaxial" is widely used to describe cable with a single center conductor and multiple shields which are insulated from each other. I stand corrected, and apologize for my error. And I've learned something today. Thanks!

First of all the antenna is not very mechanically stable. You need to guy it.

My experience with the butternut hf6v with warc was mixed. I had the antenna mounted on a 30-foot tower with their ground plane kit and 3 radials for each of the warc bands. By mounting the antenna above ground you don't need as many radials and there is less losses. Since you're interested in ground mounting it. You will need to bury at least 30 radials to get your losses down.

On 10 meters, the performance wasn't very good. The reason for this is the antenna is a 3/4 wave on ten meters. Vertical antennas beyond 5/8 wave become cloud warmers. Any vertical beyond 5/8 needs to be colinear.

The antenna was useless on 12 meters. I think it was still to close to being a 3/4 wave but I'm not a 100 percent sure. I never did figure out how the 12/17-meter kits worked. Perhaps someone in the newsgroup can explain it. I sure would like to know.

On 15 meters the antenna uses a 1/4 stub to divorce upper portion of the antenna. The antenna is a 1/4 wave on that band. The biggest problem I had on 15 was stub wire kept stretching. Thus detuning the antenna. When it was working, It did ok.

From 80 ï¿½ 17 meters the antenna worked excellent. On 17 meters I think it's a 1/2 wave but I'm not sure and 20 meters it's a 3/8 wave. On 30 meters the antenna is a 1/4 wave and 40/80 meters it base loaded shorten vertical.

MY biggest complaint about the butternut is its flimsy construction and the lack of a phasing network on ten meters. They really need to redesign it.

Best of luck

I think the symmetry of the situation would dictate that you'd get
tilted linear polarization if you feed a quad like I described,
regardless of the element circumference.

No, I've never seen the antennas you describe, but I'm not very familiar
with all the manifestations of patch antennas. A circularly polarized
turnstile is sometimes made by feeding two crossed dipoles of different
lengths at a single common point. The trick is to make the dipole
lengths such that the angles of their impedances differ by 90 degrees
(for example, 71 + j71 and 71 - j71 ohms, which are 100 ohms at +45 and
-45 degrees respectively). Then when you excite both with the same
voltage, the currents are in quadrature. You could do the same thing
with lumped components, by using equal length dipoles and adding a
series capacitor to one and an inductor to the other.

But I don't know how you'd do this with a quad element. Maybe you could
effectively disconnect portions of the loop from each other using stubs
or parallel tuned circuits, and force the necessary currents to flow in
each section.

Source record: 152560

Don't EVER consider using a multi-turn loop for a transmitting antenna. The conductor loss soars due to proximity (skin) effect. For small loops nearly all the loss occurs in the conductors.

The only advantage of multiple turns is that much smaller tuning capacitors are needed. Large-capacitance, high-voltage capacitors are expensive or may not even be available.

But it should be stated that for the same power far higher voltages occur across the tuning capacitors of multi-turn loops. So although a small picofarad capacitor may be needed the physical size of the capacitor remains the same because the spacing between the plates has to be increased in the same proportion.

How is the MFJ259 recalibrated ?

If it gives the wrong answer the only way to re-calibrate it is to buy a new one.

Reg.

I find this to be the most compelling proof that the antenna is a fraud. Consider: It's been around for, what, 15 years now? If it really did what it claimed, broadcasters would be snapping them up like crazy. All it would take to make sales go through the roof would be to produce results from a good, objective test done by respected and impartial consultants under carefully controlled conditions. The modest cost of such a test would be very quickly paid back many times over. If the antenna works as claimed, there's absolutely no reason for the inventors not to have had the test done years ago. But it hasn't. Or at least the results haven't been made public.

I personally think it's laughable and a bit sad that so many people have gone to so much effort to analyze and dissect this antenna, as though the burden of proof lies with anyone but the wizards who brought us this miracle. The clear evidence of its shortcomings is simply the glaring lack of verification of the claims made for it.

John, I have three wire antennas up at present using ladderline. I have had several in the past.

If there is a way to put up ladderline *without* it developing a twist, let me know!

I see nothing wrong with the twists, mainly for the reason you mention, plus the fact that twisted line seems to be less affected by wind.

As to rain effects, I have not noticed any practical empirical effects of water on the 450-ohm "window" line that I use. Since I operate a great deal on QRP CW with only 5 watts, any serious feedline loss would show up pretty quickly. But, I have done no valid tests to measure loss. I do notice a very slight change in tuner settings when the lines are wet, but that is all.

There are a number of multi-turn loops described (search google and then trace numerous links -- better yet, go to the AA5TB Website and you will find the links in there somewhere). Multi-turn loops, after a lot of reading, turn out to be very inefficient for technical reasons, BUT -- if that's what it takes to get you on the air, go for it. Unless you are desperate, almost any other antenna including single turn loops will provide better results.

That's my 25 cents worth!

I just bought a metal whip at AES, can't remember if it was a Maldo,Comet or Pryme, but I can tell you it is 17 inches tall, SMA connector for the VX-5, extremely flexible for my VX-5. The stock ant. was not able to hit our club repeater 7 miles away on 2mtr. but with the 17" whip, I'm at low power, sitting in my basement and able to trip the repeater. Receive is alot better, I'm tickled to death with it. Even survived slamming it in truck door, no bends, can tie it in a knot. I'll look for the model, when I get my truck back :-)

The full size G5RV was original design to be used on 20 meters
without a tuner but with a decent tuner with a roller inductor you
should be able to load up any band between 10 - 80. In your case
10-40. However, this doesn't mean the antenna is going to perform
well. The radiation pattern can get pretty wild. I would recommend you
do a simulation on one of NEC programs that are available. See what
the pattern looks like on the different bands.

When trying to work DX the goal is to get the take off angle as low as
possible. Horizontally polarize antennas need to be up 1/2 wavelength
or higher. Vertically polarize antennas are not depended on height to
achieve a low take off angle but its good idea to get them up high to
reduce losses and avoid obstacles.

As for the rfi, I think the problem is your getting current on the
outside shield of your cable. Are using a current type balun?

If not, you may want to install one. An alternative you might want to
try making a RF choke by coiling up some of the coax were it connects
to the balance line. On ten meters this might be enough to solve your
problem.

Best of luck

GW

Source record: 152476

RC, your problem lies in the 60 feet of coax. Get rid of all of it. Take the balanced feedline right into the shack or as near to the transmitter as you can get it. You will no longer have a G5RV but you WILL have a reasonable multi-band antenna system.

To analyse performance of any dipole at any height with any feedline, balanced line plus coax, plus balun, plus tuner, download program DIPOLE2. It will tell you anything you want to know about your present antenna system, including antenna, feedline and tuner losses. All except radiation patterns which for a simple multiband dipole in the average backyard can be considered omni-directional.

The higher the balanced feedline impedance the better. Use 450-ohm ladder line or 600-ohm open wire. 300-ohm TV stuff offers a mediocre performance but if that's what you have stick with it for a while.

This is Santa Claus at the keyboard. For a Christmas present dip into my website and download DIPOLE2 in a few seconds. Not zipped-up. Run immediately. User friendly.

Not true. All the 259/269 models have several analog adjustments, ahead of the digital firmware in the 259B/269 (which obviously you cannot adjust). There are details somewhere on the Web and on Deja, definitely for the basic 259 and maybe for the computing models too.

But before you try, you'd better have more knowledge and better test equipment than they have at the factory.

I just don't get it. Why is the G5RV so often "the choice" for a multi-band antenna? I see it as a compromise, and a poor one, on every band.

On the other hand, I purchased a multi-wire dipole from Alpha Delta (the DXCC) and it has resonant dipoles for for each band 80 through 10 (except 17 and 12). If I had been more motivated, I could have built one out of 5 bucks work of wire. It has excellent SWR across the bands, only requiring the built-in tuner of my ICOM rig, and it works beautifully. It only about 80 feet long (as opposed to the 102 feet for a G5RV). The shortening coils of the DXCC certainly make it a bit less efficient on 80, but still it seems to work on that band pretty well (admittedly, I don't spend a lot of time down there).

My only regret is the inability to tune on 17 and 12, which I fixed nicely by making a delta loop (51 feet of wire in an equilateral triangle hung as a flat-top with the feedpoint at the bottom vertex. This works on 17, 15 and 12 (again with my built-in tuner).

Is there something I'm missing something that the G5RV has that makes it better?

>

That is exactly how the patch antenna I described works. In one
direction it has r+jx and in the other r-jx. When fed at the corner
the reactance cancels. The current in each direction is 90 degrees
out of phase, resulting in circular polarization.

You also described the turnstile correctly. Did you see the article?
It wasn't too long ago (this year or last?) and was in CQ, QEX, or QST
(the only ones I get).

I was just speculating if the same thing could be done with a quad.
And, no, I am not talking about multiple driven elements, but just
one. You may be right Roy, it would probably take some phasing stubs
or multiple feed points. What I was thinking of would have adjacent
sides out of phase, and opposite sides in phase. I'll have to
cognitate on this one a bit.

[As a side note, I have often wondered why circular polarization is
not used for amateur repeaters, except perhaps for antenna complexity.
There is a distinct advantage for reducing flutter, and there are a
number of ways of making omnidirectional circular polarized antennas.]

Bill,

I purchased a 5 band spider Gem Quad (Canada) for several reasons:

1. All WARC bands, _and_ 6 and 2 meters!

2. Optimal (or at least better) spacing on each band. This has two effects: the SWR curves and F/B ratios on each band are a little better than the fixed-spacing quads; and the elements are a little farther apart from each other than on a fixed-spacing quad (reducing interaction between elements)

3. Ability to TUNE each band independently - so when I want to adjust tuning and F/B ratio on 10 meters it doesn't completely undo my settings for the other bands.

4. Ability to FEED each band independently - although I do not do it this way. I feed the antenna to match my rig and amplifier/tuner [Icom 746, AT500/IC-2KL] - so I coupled 10/12, 15/17, and 20 meters is alone.

5. Lightweight, tight turning radius - I have this on a 56 foot fold-over tower with a medium rotor on a heavily treed lot, and can drop it to the ground and work on it single-handedly.

6. Previous positive experience with a quad on HF... low noise, good bandwidth, great for DX; along with negative experience with trapped tri-banders (ugh!).

Now, having said those positive things, I will also add that tuning the quad is a labor of love and requires patience. I would not even attempt it if it were not easy to drop the quad and adjust it (crank up, fold-over, whatever - or you gotta' love climbing towers!) and unless you own an MFJ 259 antenna analyzer.

Back in the early 1970s, when I was an undergrad, I worked at the Ohio State University ElectroScience Lab. At that time the army was still using a lot of HF and low VHF back pack radios. These had long whip antennas. They (the Lab) developed a multi turn loop antenna as a replacement. As I recall, it was about a foot long and maybe 6 or 8 inches across with 8 or 10 turns of 1/2 inch copper pipe. However, I only saw it once as I was not working on the project myself so I don't know the details.

Of course, it would be inefficient, but when someone is shooting at you you don't want that long whip waving in the breeze!

Could it be that in a high (electrical) noise environment you would
ground the outer sheild at one end only?

I have seen this technique suggested for such cases.

I have an HF6V ground mounted with 25 radials, about half are 25 feet and other half 16 feet. I have worked DX on 15 meter and get respectable SWR on 15 and 10. I do not have the 12m and 17 m kit. I am able to work 12 meter with use of the internal tuner on my Kenwood. On 17 meter SWR is skyhigh and Kenwood tuner doesn t help. My MFJ tuner gets it down to workable limits. I have worked all over the US on both. 40 meters upper band I get 1.5 SWR without the use of a tuner and am able to get out pretty well.

Jim:
This is a technique used by broadcasters in the early days for audio wiring, and still hangs on among those who haven't gotten in trouble yet. It works where there is only 60 Hz present, particularly well if there is an iron core transformer at each end, but the open ended shield acts like an antenna at HF, and can cause real problems in high speed data networks. Or even in audio systems, as it is rare to find equipment which rolls off at 20 kHz anymore. I was involved in fixing an audio system which had IMD problems arising from Megahertz range signals entering the wiring and overloading the front end of the audio switcher, which exhibited useful gain to about 4 MHz. This is an AUDIO box, for gosh sakes. The general mistake here is trying to use single ended connections between chassis which are at different potentials and suffering the common mode problems as a result. The correct (and expensive) approach is to have all signal interconnection circuits balanced, use shielded twisted pair (or Twinax as I pointed out to Roy), and not include chassis potentials in the signal loop. But manufacturers are slow to learn, and few if any have any experience operating their equipment in an extended plant. I swear they develop hardware in a vacuum, as real world problems seldom get addressed until after field problems arise in a complicated installation.

Howdy Everyone,

At a swap meet I picked up a portable antenna mast. This thing is really cool, it has a big tripod base that folds out. There are two mast sections that fit on top, then it slides up to put an antenna about 20 feet in the air. Whole thing folds up and slides into a carrying bag that's a little over 5 feet long and 8 inches wide.

Over the weekend I attached a 3 section 10 meter vertical to it, and worked a few stations in the contest, including Luxembourg on 25 watts (my very first DX contact!).

Another fellow (thanks to Dave, W9WI for the idea) suggested I get some other mobile antennas to mount up there, so I could work other bands. Great idea for field day or when I am away from my QTH.

I was looking at the Hamsticks on their site (www.hamstick.com), very inexpensive solution (25 bucks). Was wondering if anyone had used these, or if there was some other brand I should be looking at.

Also, since I'll have it way up in the air, and not attached to a vehicle, do you think I'll need some sort of counterpoise?

Thanks,

Robert / N4IXT

Without knowing how your building is constructed, and what the surrounding terrain looks like, there is no way to give you an honest opinion. What is causing the path losses (snow on a line-of-sight path). What is causing the multipath (ghosts), nearby mountains causing reflections?

In general, your best solution would be a directional outdoor antenna mounted
on your roof clear of nearby obstructions.

Robert,
It should work out fairly well. And, yes, I think a couterpoise would be a good idea. It might amount to a simple wire 'hanging' from the base of the antenna. Who knows, give it a try and see...

Big is talking mildly...

I tried this and learned that you better use at least 3/4 inch copper. I started out trying to use 3/4 to 1/2 reduced for looks and raising it was deserving of using a helicopter. And the 1/2 inch section was so flimsy it bent right in half. 3/4 for the entire thing is a better idea.

I guess this why they call it experimenting.

>reasonable multi-band antenna system.

If you are saying that because the coax is removed and replaced by
balanced line the antenna is no longer a "G5RV" then you are
incorrect.

Varney proposed this very configuration in (fig 2) the very first
article he wrote on the subject.

I have better things to do than to constantly maintain a web page so I
don't have a link to it but if you go to:

http://users.triconet.org/wesandlinda/g5rv.pdf

you can read the original paper.

Since the *only* thing special about Varney's antenna is the "magic"
102 foot length, the *only* antenna that can properly be called a
"G5RV" is a 102 foot long, center-fed dipole.

Besides "G5RV"s there are "YAGI"s, "MARCONI"s, "W8JK"s, "LAPORT"s,
"ZEPP"s, "WINDOM"s, "BRUCE"s, et cetera.

But henceforth, all other center-fed dipoles, whether fed with coax
(with or without baluns (choke, current or voltage), ladderline,
twinlead, or zip cord should be called by their proper name: "N7WS"s

Please update your software accordingly. Thanks.

I've had it with SWR. Ever since I was a kid and bought my first Midland base station, then decided a 3 element beam on a 40 foot tower would be fun to have, I've been haunted by high Standing Wave.

When did I ever do somethng so wrong in my life, that my punishment would be never seeing the ratio less than 4:1 ever again?

At 45 years old, you'd think I'd have the fortitude to correct such problems, but it seems that I haven't learned to patiently think things through since my 15th year on this planet.

Just last week I put a radio into service and gingerly erected an Antron A-99 on a 20 foot mast next to my Florida room. When I checked the standing wave, yup you guessed it, 5:1.

Manufacturer said, "Wow, that's wierd...should be 1.5:1 at 27.385MHz..."

Really?!? Gosh coulda fooled me...

So I figured an antenna tuner would help, since I didn't want to turn those tuning rings on the antenna for fear of screwing something up. With the tuner I was able to get the SWR to 1:1, but the radio only puts out 1 watt now.

Sigh. I'm doomed.

As an early Xmas gift, I have been given a little cell-phone antenna that lights up and blinks when there is an incoming call.

So, what I'm trying to do is remove the original antenna from my cell phone, and then stick in the new antenna.

Question: how do you remove the standard antenna from a Nokia cell phone? Just pull the little bugger out? I don't want to damage anything.

> longer a >"G5RV" then you are incorrect.
>
==========
I did NOT say that if coax was removed it would no longer be a G5RV. Indeed
if that was all which was done to it it would still be a G5RV.

But Mr Varney, in addition to specifying length of the top (3/2 wavelengths
on the 20m band) also specified the length of the balanced feedline.
(1/2-wavelength on the 20m band}. If the balanced line is lengthened to
replace 60 feet of coax then quite obviously it is no longer a G5RV.

Apparently you are not aware of this. I suggest you yourself should find
time to read Mr Varney's papers you recommend to be read. My response to
your comments must be disappointing. Sorry !

To analyse performance of a dipole+balanced feedline+choke balun+coax+tuner,
download program DIPOLE2 from website below.

>Sigh. I'm doomed.

Hi Jim,

If you can pull the SWR down to 1:1, your rig shouldn't have any
problem applying full power - unless there is something wrong with the
rig, or the SWR measurement, or the power measurement.

The last two are far more probable sources of confusion/grief. This
then hinges on how and where you measure either SWR or power. You can
confirm both by placing a dummy load at the far end of the feed line
(literally replacing, and thus eliminating the antenna) and making
power and SWR measurements of it. You should also attempt to "tune"
the dummy load with your tuner. There should be no surprises. If
there are, move the dummy load closer to the rig (eliminate the
feedline). If problems persist, move the load to the other side of
the tuner (eliminate the tuner) and measure again. If this last

elimination round saw the SWR/Power meter go, use a friend's (substitute the tuner). If problems persist, it is almost certainly the rig - or sumpin' else.

One common problem that lends itself to confusion is the lack of choking of the drive point from the feed line. A simple test for this lack is to vary the length of the feed line and observe the SWR (and changing nothing else). If the SWR changes (it shouldn't) then you need to choke the drive point (and it will clear up a lot of odd behavior). One test could be conclusive, but if you happen upon a "magic" additional length of feed line that merely repeats the already observed values, you may be fooled. Thus try with at least two different lengths; and if SWR does NOT alter appreciably (we are not concerned with a fine distinction here), then the drive point appears to be sufficiently isolated from the line.

Note that these lengths that I speak of are at some level of discussion, implicitly related to wavelength and you need to be aware of how provide for non-resonant sections. Or simple keep throwing odd lengths into the mix and measure the SWR.

If the SWR changes, throw a few loops into the feedline just at the drive point. This is the simplest, cheapest fix; but be advised you run the risk of achieving the optimal solution as easily as an indifferent one. If you wind the choke with more attention to forming a long solenoid (8-12 turns of 4 - 8 inches diameter is the convention); then you are far more likely to have satisfied the isolation requirement. Another, popular, option is to use a 1:1 current BalUn which can easily replace the solenoid.

|
|Apparently you are not aware of this. I suggest you yourself should find
|time to read Mr Varney's papers you recommend to be read. My response to
|your comments must be disappointing. Sorry !

Reg, you never disappoint me but you often amaze me <g>.

I'm looking at figure 2 of the paper and it clearly states, "Convenient length
of open wire feeder (preferably an even or odd multiple of quarter wavelength at
14 Mc/s."

In the text, Varney states: "Alternatively, open-wire feeder maybe employed from
the centre of the aerial right back to the transmitter output or a.t.u."

So I suggest that *you* read the paper before suggesting that I misread it. The
last time I checked, "Convenient" in this context means "any" and odd multiple
of quarter wavelength doesn't mean "1/2 wavelength".

Now when are you going to write a program: N7WS.EXE?

Cheerio,

N7WS

You might fish around on groups.google.com. Gary Coffman used to be a regular on this group, and he apparently owned or managed a number of FM stations. He mentioned several times regretting converting from linear to circular polarization. I don't recall exactly what the problem was, but he felt strongly that it had a negative impact on listeners. So there's apparently a real-world down side that doesn't show up in simplified theoretical models.

I made a slinky doublett using to slinky's and fed it in the centre using
300 ohm twin,using a balanced atu i found i could load it on all bands
except 160.I have it in my roof space and it works quite well with powers
upto about 50watts.I guess if you could get it outside it would let you use
higher power.Overall length i have it stretched out about 4mtrs,but you
could shorten it or pull it out longer.I have a plastic clothes line running
between the ends to support it..

If the thing is going to be able to tell which of the millions of
signals flying around out there are destined for your particular phone,
it's going to have to connect to the phone's innards in places other
than the antenna connection. I find it highly unlikely that a
manufacturer would turn a job like that loose on the average consumer.
If it is something intended for hobbyists willing to perform surgery on
their phones, it should at least come with highly detailed instructions.
Based solely on what you've posted here, I'd wager that whoever plunked
money down for that miracle antenna was scammed.

IIRC, these things work by detecting the higher-powered signal
from the phone when it's talking with the local cell station
while it's ringing.

Wes and Richard,
If the coax portion of the feedline is removed, the antenna
is indeed no longer a 'G5RV'. Parallel line feedlines to a 1.5
wave length doublet predates Mr. Varney by quite a few years.
As to why the 'G5RV' is touted as an all-band antenna, as
someone else said, 'hype', typical 'untrue' advertising, the
seller
wants to seperate you from your money and cares little about how
he does it.

UHF channel 22 is different from CABLE channel 22.

On some older CATV systems the carriers are HRC spaced, and channels 2 to 13
are not exactly the same as air channels 2 to 13. Some Televisions require
you to set IRC or HRC or Broadcast in a menu.

We often get trouble calls that are resolved by putting the tv back in the
correct mode.

with the antron, first you cut it to length. They don't say wether you measure from the top, or the bottom of the metal junction, and that is over 2 inches long, plenty long enough to cause the grief. AFTER you are cut to the right length, then you tune the rings. Mine is reasonably flat.

When I bought my Antron, nothing would cause it to tune and it did not recieve well. I found no continuity between the pin and the shield. I went back to the store, and had them pull another one from stock. There was around 0 ohms from pin to sheild. I exchanged the antenna and the new one worked just like the book said...

All of the other responses are good ones too.

That is no doubt true, but Mr. Varney has been associated (by others I'm sure, I doubt that he was so immodest) with this particular genre of antenna.

I don't have this problem so I can (with tongue planted firmly in cheek) claim all versions of center-fed dipoles, of length different from 102 feet, as N7WS type antennas. I have been using them for 50 years and no one else has laid claim to them, so I will "boldly go where no one has gone before."

Yes, and the stock market is in the dumps, so I want in on the gravy. I think I'll put up an "official" N7WS antenna page and start raking it in.

I use a personal stereo a while riding the train. the RFI to my stereo is strong enough, and early enough, that I wake up and turn off the personal stereo before the phone even rings. Even happened once when the guy next to me got a call!

As for the Nokia, we have three in my family. On one the antenna extends and I think is easy to change. On the other two, they carry warnings in the owners manual not to try and extend the antenna as you will damage it and the phone when you pull on it.

That's what my Nokia owner's manual says -- don't try to extend the antenna. But
I thought there might be some simple trick to getting it out. Maybe I'll just go
to a phone dealer.

4272. Re: any info about EH?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-20 22:29:03 UTC
From: stefano <sgalast@tin.it>
Message-ID: <PCtU7.23348$o9.792009@news1.tin.it>
Source record: 152424

Hi Roy, How are you?
stefano Ik5IIR speaking.

Since my italian first introduction on the EH antenna , I finally got
satisfactions from several ham .
They built some eh on some different frequencies and experienced exactely
what I am saying.
They did several comparisons against full dipole and short loaded antennas
used as reference.The figures they got are perfectley compatible with the eh
features.
these are facts. they are absolutely indipendent persons.

Roy , they were astonished.
Considering the interest we have in Italy, I am sure others will come soon.
I have time, I am not in hurry.
I am sure very soon you will see some perfect realization in USA also.

Excuse me If I insist, but the eh antenna is real, almost 100 % efficient,
can be 0.5% lambda on size, can have a wanted pattern,
very high S/n on rx. and so on...

The big obstacle still present on this antenna is the working principle....
I know is so new, so different, is normal get upset comments.
But we changed our strategies...now we are saying:
since is working exactely as we say, please explain why.

I am sure very soon you will see one of them working ok in the USA also...
Actually there is nobody pushing it there...Ted Hart is still ultimating the
medium wave version for the FCC test.
I think at the beginning of the new year you should hear something from him.

I wish you a merry Christmas and happy new year.

Sorry, I don't believe it.

If you want to convince real engineers, or anyone else with even a small sense of skepticism, you need a different strategy. You don't need to explain how it works at all. You don't need to post testimonials to Internet news groups or publish articles in 73 Magazine. All you need is to publish the results of a professionally done, objective measurement test in a respectable journal. That's all. If it shows that the antenna really works as claimed, there'll be hordes of Ph.D.s and Ph.D. wannabes pushing and shoving each other out of the way to be the first to publish a rigorous explanation of how it works. The papers will virtually fly out of their word processors. And the money it cost to have the test made will be made back so fast it'll make your head swim. In no time flat, the EH and CFA inventors will be living in big villas by the ocean, sipping the finest booze, just like the folks on the late-night TV infomercials here in the States. What are you waiting for?

Be sure to let us know when the results are published, and in what journal. In the meantime, the glowing testimonials are so much QRM. Oh, and could I perhaps interest you in some fine real estate?

Um.. you're wrong.. I was never an illegal keyclown, but then again, I don't expect you to know the difference. I ran the legal 40 with legal power and with legal gear.

You can call names all you want, but it doesn't change the truth.

But you're right. I did go from CBer (which I ran sideband for a bit over 20 years, and ran professionally) to extra in 6 months, 1 week, and two days. Of course, I worked hard for nine years (I started drilling the code in '92) to overcome my dyslexia so I could pass the code requirement.

What of it?

Sounds Like a story for QRZ or 73 magazine. Perhaps you can get Twisty to
author it, and any money made off the idea I will recieve my normal stipend
of 25%.
I have applied for a copyright so don't think your gonna pull a fast one on
me and sell your story without paying me.

4279. SWR Meter Info Needed

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-21 00:22:53 UTC
From: wess@gtii.com
Message-ID: <u2506u66mv66e5@corp.supernews.com>
Source record: 152432

I am trying to tune a j pole and a mobile antenna and can't get my swr meter to show anything better than 2.8:1. So I wonder if the meter is working correctly.

The R/T is a FT-50r which puts out 5 watts on 2 meters on a fresh charge. Until I can afford better it serves as base, mobile, and hand held.

Is there a way to verify that the meter is even working? If not, are there plans where I could use it's parts to make my own for use with low power on 2 meters (440 also would be nice). Right now I have more time than money so building one might be fun.

Thanks,

Wes

KC8SPR

Dee Wesser wrote:

> here we go again... SWR is the RATIO of power sent to antenna and power not
> accepted and sent back ... SWR DOES not CHANGE WITH POWER!!!!!!!!!!!!

Right. Wrong. Right in theory, when you exclude stuff like water
in the coax, corrosion at the connectors - anything that can form
an added (or subtracted) R when exposed to higher power.
But in practice, those things can, and do, exist and cause the ratio
to change with high power vs low power

Plus, it's not a "here we go again", regardless. The poster was
asking about what he observed. The answer is not "here we go
again ..." etc. The answer is that either he's got something wrong
with his measurements (cockpit error, cheap SWR meter with
diode differences, whatever) or something wrong with his
antenna/feedline (water, corrosion, etc.). See some of the replies
addressing cheap SWR meters.

well you should buy a $100 radio and a $2,400 antenna system you will be
suprized in what you will hear and work

antenna is 99.9 % of your capabilities

just dont understand why pepole put these $ 2,000+ radios on a $30 antenna

Stephano apparently still has extreme difficulty distinguishing between the English word "fact" and the English word "statement". Even "opinion" seems to enter in somewhere. Perhaps the Italian equivalents of these terms have a closer meaning than they do when used in English.

Merely reciting a list of claims is not the same as reciting a list of proven facts, backed by detailed procedural explanations and raw data.

As to the "strategy" of not explaining how the EH works, I am not at all surprised at that. The Flat Earth folks had similar problems several hundred years ago . . .
but they sure talked a lot.

As Roy says, we don't need involved theories right now. But, as a practical matter, how does one make a patent application without at least enough theoretical background of the invention to satisfy the PTO? Remember, the description must be sufficiently detailed that anyone reasonably skilled in the art can duplicate the inventor's device and performance.

As Officer Friday would say, "just the facts, sir, just the facts." That comes from an old TV series here in America, Stephano - it became a catch phrase that many used when seeking facts rather than claims.

Ah, those were the good old days. To get an idea of what's required to get a patent these days, have a look at U.S. Patent #6,025,810. The following URL will take you there, but you'll have to paste it together to remove the line break(s):

http://patft.uspto.gov/netacgi/nph-Parser?Sect1=PTO2&Sect2=HITOFF&p=1&u=/netahtml/search-bool.html&r=1&f=G&l=50&co1=AND&d=ft00&s1=''6,025,810''.WKU.&OS=PN/"6,025,810"&RS=PN/"6,025,810"

Or you can just go to http://uspto.gov and do a search for that patent number.

The existence of a patent is in no way evidence that the patented item is useful, practical, or even possible, that it can be built, or that it can or does work as claimed. I've read many, many patents, among which were quite a few that couldn't possibly work as claimed. But it usually requires someone with detailed knowledge in the specialty (which doesn't describe patent examiners) in order to see that a device is impossible. The nice thing about patent 6,025,810 is that its shortcomings are a little more obvious. Hopefully.

Hm, actually, maybe it works on the same principle as the EH antenna. .
.

Dear Middie:

I've been licensed longer than CB is old. Elmered a batch of freebanders
over the years and all of them were decent amateurs. If his coming out of
CB is supposed to disturb my digestion, sorry. The numbers game alone
assures that most people becoming radioactive do so via CB.
He seems to have handled his problem; can you say the same??

My, my. Aren't we ignorant of pop culture.

FYI, I was referring to the troll dolls that were popular in the 70s. They were those little things with the big eyes and different colored, Don King style of hair. Smaller ones were often on the ends of pencils, or on keychains, or hanging from rearview mirors. They're still around, but not as popular as they once were. Although they did have a resurgence in popularity about ten years ago.

Doc,

On replying you should include enough of the message you are replying
to so *any* reader of the news group can understand what you are
talking about.

You don't need to include the entire contents of a previous posting in
your reply. Cut out as much as you can while leaving enough of the
original to make it clear what you are responding to.

That is basic NG etiquette.

Remember, it is possible that other NG readers will receive your
response before the original message you replied to arrived at their
server. That happens often.

I have an SB-401/ SB-303 pair that has been sitting around for a while.
Is there someone in Canada (I'm in Ottawa) that can go over these things
and bring them right back to spec?

Thanks,
Rob

I am considering picking up a Radio Shack Discone for 6 meter FM work. I am not overly concerned with high gain or far DXing on FM. That's what I've got my yagi on SSB for. Can anyone tell me anything about this discone antenna? Supposedly it will work everything from 50 mhz - 1.2 gigs... any input is appretiated.

Yes, you would need radials. And they need to be resonant to do their
job correctly. But you can get by with only one per band used. Of
course , more is better. In some case radials for a lower band can
function as 3/4 wave radials on a higher band. But I wouldn't use
hamsticks. I'd make a lightweight vertical and feed it with a base
loading coil for many bands. IE: gothom vertical type of thing. If you
make the antenna about 20 ft tall it's a 5/8 on 10m. You could work
down to 40m with decent results if you had a few radials. A 20 ft
aluminum whip and a lightweight Hi-Q coil would eat a hamstick for
lunch. Even my super fortified hamsticks..:) My tallest mobile config
is 13-14 ft tall. The average hamstick will be much shorter and use
narrow lossy coils. In many cases a dipole hung from that mast as an
inv vee would be even better. In fact, for 80/40/20 I'd probably go
with dipoles strung from it. The 40 will work 15. I have a setup kind
of like that for portable use. I have a drive on mast holder that uses
either rat shack tv mast or fence top rail as it's cheap. I use the
fence rail. At 5$, I can bend one, and it's no big deal to replace.
Two of them are 20 ft. I found 30 ft hard to deal with...Too top heavy

with even a small 6m yagi. 20 ft is super easy even with one person. I also have a short crankup tiltover tower for industrial strength portable use.:) I used it at FD last year with a A4S on it. It will fit in the back of my truck with the gate up. It's in my garage right now, standing up! I think it's 7 ft tall retracted. It's very stout and stands up by itself no problem even with a beam on it. I have a real heavy baseplate for it. Of course, I put a 3 rope guys on it just to be safe. I'm getting to where I like portable/mobile better than operating here at the house. If you get a hamstick, put it on the car where it belongs. :/ MK

Sorry, just couldn't resist. I haven't seen anything on
an '8010-B', so can't be any help to you. I can say this,
though,
a vertical antenna on 80 meters is just ~not~ going to be the
antenna of choice most times. At least not without a lot of work
on a ground system. Most vertical antennas just don't 'do' 80m
very well...
'Doc

Hi Roy,
ah ah ah..:-))))
thanks a lot for all.
I really appreciate it.
Yes I know and I understand what you mean.
I need more time for that, but for sure I will.
Roy I have the power of truth pushing me, I have a really busy schedule
here, because I am going to production.
After so many happy hams saying me the antenna is amazing, I decided to
recover some money I spent for research.
Hence I am very busy.

after all please think what ham are doing every day....
they push the PTT , speaks on it then hear what the other ham in other side
of the world , say.
You can use the CW, the psk 31 and so on...
Well , Roy, a 1 foot eh antenna on 40 or 80 or.... do this very well having
the same signals report than a traditional monster antenna.
That's it!
I think it's worth a try.

Do you know what is my dream ,now?
Have you so skilled guy , here beside me sharing this fun, jumping around
with me, shacking hands and drink some good italian wine in front a goos
steak.
NOT for me , NOT for my business, BUT for all the ham community...
I am restricted, I am living on a big city, how many problems hamming around
of it!!!
Hams are waiting this since ....ever.
Now the wait is over.

I wish you sincerly all the best to you and your family for a peacefull
Christmas.
I put my dream under of my Christmas tree....
We will see in the future...
ciao and 73 de IK5IIR

I am now accepting orders. Overseas shipment is confirmed. 20 3'
antenna and feeds to arrive in about 14 days. 10 taken.
I have worked very hard to bring these antennas into the country after
they were made to my design. These antenna are NOT BBQ grills posing
as microwave antenna. These are the real thing. I'm not a big
company, i'm just a Ham like you trying to fill a void out there. I
was amazed that there wasn't a single company making anything of real
quality for AO-40, so I thought I would give it a try. I hope I am not
offending anyone by posting here. I'm just trying to get the word out
and save possible customers the cost of advertising.

Drop by my new web site and look around. Leave me a comment if you
like.

Hi Wes,
try to measure a dummy load instead of the feeder and antenna. You
must get SWR nearly 1:1, otherwise your SWR meter seems to be corrupt.

BR and merry Xmas from Ivan

According to the catalog, it uses a resonator to tune 6 meters, so you might be losing a little power there. If you're looking strictly for 6 meters from this antenna, something like a j-pole would give you good omnidirecitonal coverage... http://home.houston.rr.com/w5met/antenna.html

On the other hand, if your repeaters are nearby, it might not matter.

Let me clarify....

What I meant was that the inner shield would be connected at both
ends, but the outer shield at one end only.

Like you said, the best way is to use shielded twisted pair with, I
might add, two isolated shields with the outer shield grounded at one
end only.

Well, have to get to the break room before all the donuts are
gone....The people here are real vultures!

I don't have the Radio Shack disconne antenna, but I do have one made by Diamond. The Diamond disconne comes with a vertical element that the RS antenna did not come with a few years ago. I haven't looked at the RS antenna lately, but I would check to make sure that the vertical radiator is included. It will not work without it, unless they have significantly increased the size of their disconne (the best way of doing it).

The Diamond disconne does work on six meters, but within a very narrow frequency range with an acceptable SWR. If you live close to the six meter repeaters, you'll probably be satisfied with the Diamond disconne. When the band is open, anything goes on six. Big antennas and lots of RF power are not needed at all. Good luck.

Wouldn't two per band be a lot better? Two radials with currents
going in the opposite directions will tend to cancel each other
while a single radial will radiate most of the energy?

>
> BR and merry Xmas from Ivan

you can solder a 25 ohm (or a 100 ohm) resistor on the end of a piece of coax (use very very short leads) and check the SWR.. You can use other values of resistors to check different SWRs.

From the ARRL Antenna book:

SWR = A + B / A - B where:

A = sqrt [(R + Zo) squared + X squared]

B = sqrt [(R - Zo) squared + X squared]

R = resistive component in ohms
X = reactive component in ohms
Zo = characteristic impedance of line (for RG-8 use 50 ohms)

Since when using resistors only, there will be almost no X (use 3.5 MHz). So, just remove it from the formula and make it easier.

Hope This helps

This patent has been mentioned a number of times. Does anyone know if
the "owners" did the whole thing as a gag? By the time the description
gets to the "aids plant growth" part it certainly becomes fun.

Assuming it was a gag, I think they have done a Good Deed. In the
fullness of time such nonsense may help educate the Washington
establishment about the astonishing degradation of the whole U.S. patent
arena. (IMO, the problem started with software patents, but that is a
long & serious discussion not suitable for this forum.)

I have looked all over the place and having a hard time find this information, so any feedback would be appreciated:

Can a reading at uV be converted directly to uV/m? The same would go for dBmV, dBuV, dBm , dB, can reading taking at any one of these unit be converted directly to uV/m?

Thanks

Hi Andy

Save your money!
Although they work OK for VHF/UHF scanning purposes, they fall apart quite rapidly. I have some pieces to a couple of them right here on the floor of my office.
Neither of mine could transmit on 6 meters and reception was poor compared to even a simple 6-meter J-Pole.
You could build a Halo, patterned after the old Saturn VI without too much trouble and have an excellent antenna, cheaper.

Source record: 152280

I made folded dipoles for 20, 15, and 10 meters out of 300 ohm TV Twin Lead. They were able to handle 100 watts with no problems and are pretty wide banded so tuning them with a tuner is really easy. I did find that I had to use separate feed lines for each one so I used a couple of automotive DPDT switches to easily switch from one to the other. There are more efficient antennas out there, but if you are restricted in space and/or money and your primary objective is to get on the air, they work very well.

>

Hi yerself, Bo

I visit with my wife over 5+ miles using the VX5's duck on 446.00 (she's in an automobile with a 3Db mag-mount on the roof). I also used it briefly to drive an 80W RF amp into a Cushcraft base antenna via a SMA-BNC converter and easily accessed the same repeaters as I do with my 45W mobile. Based on that, I bought a 2-band amp to use with the VX in my truck - no experience yet but anticipate good results. Haven't tried 6m yet ... maybe this weekend.

The "noise" issue is debatable. I haven't modeled the antennas at various heights, so I can't speak to the performance differences there.

>The gain on both antennas is very close.

Which is what I'd expect.

>The only negative I can see of the quad is it doesn't handle bad
>weather as well as the yagi. However, I was monitoring a QSO in which
>one of the hams was from Alaska. He was using a quad and said it held
>up to the wind and ice just fine.

I can believe that. It's all a matter of construction technique. In this regard I tend to think a quad with more than two elements is a bit of a hassle, though I give the GEM quad high marks for good design technique.

>I would like to hear from the group's experience and knowledge of the
>pros and cons of these two antennas in comparison to each other.

First, if you're comparing a trapped yagi to a quad, know that the traps often do not weather well. Further, there are losses associated with using the traps, even when they're new. On the other hand, a quad antenna typically has multiple loops which can be fed separately. There are no traps, and no gamma matches. Electrically, a quad antenna is easier to keep running well.

One other nice thing about a quad: for very little extra overhead, one can switch polarizations.

Mechanically, well, I've seen multi-band multi-element (greater than two) quad antennas. It looked like it would be a royal PITA to keep one up in the air. Of course, I saw it in a place where the weather is quite temperate and mild year-round.

So if you're limiting yourself to just two elements, a quad is often a better bet electrically, and probably slightly more difficult to keep in the air as a two element yagi.

Source record: 152284

Jim:

Single shielded cable has limited shielding effectiveness, and floating one end of the outer shield can produce RF potentials which easily exceed the shielding effectiveness of the inner shield. Best to ground both ends unless it is already inside a shielded enclosure, where the environment can be controlled.

Everyone needs to experiment with 100 foot long parallel runs of RG-58, terminated in 50 ohm shielded terminations on the far end. A signal generator and receiver will quickly inform about how porous single shielded cable is. Then try double shielded, and finally Heliax for a full education.

I brought one into the flock this year.
He's sold his galaxy rig, and bought an HT :)
I loaned him an HT, and spotted him some 9914 feedline, and a three element quad to get started.
Every year, I try to get three or four people licenced.

I agree the discones (from any source) seem overpriced, but I find them a nice antenna to have in my "go bag" because they are so broadbanded. In an emergency, I would probably be called on to help restore communications locally, and not necessarily in the ham bands. The discone plays acceptably well from 2M through cell frequencies, so it covers the local 150 MHz and 800MHz frequencies nicely.

It's also quick to put together, which is a plus.

I don't reccomend it as an everyday antenna, due to low gain, and less than industrial construction.

Peter,
Most of the problems are hills and and to a lesser extent bounce from
a few taller buildings. I agree that directionality will help a lot,
but gain should not be a problem, and an outdoor antenna shouldn't be
needed because the reception outside (the house) is the same.

For receive only, a slinky antenna does a superb job.

Two slinkies, one piece of coax, two alligator clips, some string and a few nails or staples.

Use it like a dipole.

I have the RS discone and on 6 meters there is not a very
good match. Don't have meter for 6 meters but on Bird 43
with HF slug it shows greater than 2.5 SWR. My FT847 shuts
down to 1/2 power due to mismatch.

It's better than announcing you are using WindowsME/98/XP which would
require no testing at all - walk right in! Merely undocumented
security features - pay no attention to that man behind the curtain.

My MS box went brain dead overnight with just the desktop open, the
Linux box next to it has been running continuously since Oct. 2
running at least 4 servers and several open applications in its GUI.

> > Can a reading at uV be converted directly to uV/m?

In general, no. Voltage (uV) is a measure of electric potential and volts/meter is a measure of electric field, or potential gradient. They are fundamentally different quantities with different dimensions and cannot be directly converted into one another.

An antenna can be thought of as a transducer which couples a radiation field with a field strength measured in volts/meter, into an electrical signal whose amplitude is measured in volts. The transducer, or antenna, 'gain' can be defined as the ratio of output signal voltage to input field strength. Of course the gain depends on antenna geometry, polarization, radiation angle and termination characteristics.

Sometimes the gain is called effective height since it has the dimensions of meters
(v /(v/m) = m), and in certain cases can be related to the physical dimensions of the antenna.

For example, the effective height of a grounded vertical antenna which is short compared to a wavelength and terminated in high impedance is equal to half it's physical height. A one meter high vertical immersed in a vertically polarized electric field of 1 v/m at low frequencies will exhibit an open circuit voltage of 1/2 volt. Increasing the physical height to two meters will double the output voltage. Adding a top hat can increase the effective height up to, but not exceeding the physical height.

The concept of effective height is not limited to linear antennas. The effective height of a small loop antenna equals 2 * pi * N * A where:

N is the number of turns
A is area (m^2)

Doubling the diameter (quadrupling the area) will increase the output voltage by a factor of four rather than two as might be expected from a simple dimensional analysis.

I have my PCR-1000 using one on a 20' mast in my back yard. It
works well enough from BC band up to where the coax losses start
cutting into the signal, up around 900 MHz. I certainly have no
difficulty pulling in 10-, 6-, and 2-meter stuff. I also have no
trouble listening to the Air Force GHFS on 11.175 USB, and the
local BC station at 640 KHz. And, I might add, to WGN Chicago as
well, on good nights, from just south of Oklahoma City, OK.

I'd buy another one.

I'm suspicious when anything like that offers "superior bandwidth",
particularly when you're talking about 300 ohm TV twin lead.

Unless you're dealing with a cage or a butterfly dipole, I see no
reason to think that a folded version of a wire dipole ought to be any
better or worse in bandwidth. Since you point out that it was "pretty
wide banded" I suspect that the efficiency was probably not too good.

Were you able to compare it to an unfolded dipole? How did it stack
up?

4349. New concept for mobile antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-21 20:16:42 UTC
From: arm@helix.nih.gov
Message-ID: <KMMU7.433$%D6.550158@mencken.net.nih.gov>
Source record: 152301

Tell me if this is a new concept. I think it is pretty darn cute:

To operate a HT inside a car without having to connect the HT
directly to the antenna feedline, why not put an antenna inside
the car cabled to an antenna on the roof. For example, if you
put a BNC bulkhead female to female connector on the roof of
your car, you can put a 1/4 wave whip on the outside connector
and a rubber duck on the inside end of the same connector.
You could then use your 2m HT inside the car and this passive
antenna system will re-radiate the signal to the outside.

I would love to put up a 70' tower with a 7 element beam, but due to
CCRs, antennas are not allowed in my neighborhood. Although the G5RV
cost $15, it works well on 20 and 40 meters, and IT IS LOW PROFILE. I
don't have any complaints from my neighbors, and it is unseen from the
front of my home. I hope that helps.

Myself.

However, I do not use applications (MS products of course) that are
common virus, or trojan horse vectors.

As far as virus detection goes, I find that class of software as
useful as security by autopsy. "We've discovered a new virus! But
lost the first wave of 10 million patients."

|
|Hm, actually, maybe it works on the same principle as the EH antenna.

Or the following:

I have before me a brown bottle of familiar shape. The bottle is filled with a liquid and the top is sealed with a stopper that is held in place with a twisted wire that is in turn covered with red metal foil. On the neck of this bottle is a paper label that states: "Guaranteed Under Food and Drug Act June 30, 1906. Alcohol 1 90/100 percent. Anheuser-Busch Brewing Association, St. Louis, MO.

On the body of the bottle is a colorful label with the well-known eagle inside the block letter A. The product is called "ANHEUSER-BUSCH'S Malt-Nutrine, A Non Intoxicant. Sparkling. A Highly Concentrated Liquid Extract of MALT and HOPS. Dose: A wineglass before or after meals."

On the back of the bottle is another label that describes what we might call the "claims" for this patent (medicine).

"What ANHEUSER-BUSCH'S Malt-Nutrine does.

M akes blood and tissue
A ids digestion
L ends strength to the weak
T riumphs over disease

N ourishes the convalescent
U surps the place of nauseous medicines
T ends to produce refreshing sleep
R ests the brain and quiets the nerves
I t is invaluable to nursing mothers
N othing like it for teething children
E nriches the blood and builds up the system.

Signed Aug. A. Busch"

In our travels around the country, my wife and I have visited several A-B breweries and taken their tours. (Anything for a free beer) Not once have we ever seen one of these bottles in their historic displays of past products. Perhaps they are ashamed of the outrageous claims (although a couple of them work for me) and have avoided public ridicule.

Too bad the Fractured/EH guys don't take a clue.

Only one thing wrong. It will radiate less to the outside than
the rubber duck.

Bob,
Using your tuner, almost anything will 'work'. But how well
does it 'work'? I'm willing to bet it doesn't 'work' very well,
or at least not as well as it could/should. Especially if you
have limits, I would think you would want the most efficient
antenna you could get. Surely, this isn't it.

4358. Re: Do "folded" folded dipoles work?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-21 22:26:24 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C23B710.87D1CCF0@eznec.com>
Source record: 152309

A folded dipole has a wider bandwidth than a single wire dipole because of its effectively larger diameter. Two #20 wires spaced 0.3" as in common TV twinlead is equivalent to a single wire of 0.145" diameter. A quick run with EZNEC showed a 10 meter twinlead folded dipole to have a 2:1 SWR bandwidth of 2.4 MHz. A single dipole made from #20 wire was 1.9 MHz, #12 wire about 2.15 MHz, and from a 0.145" diameter wire, 2.4 MHz. These all assumed that the antenna was matched at the point of resonance.

You can get just about the same bandwidth in an unfolded dipole as a folded dipole by making the unfolded dipole with twinlead, connecting the two conductors in parallel to make a single equivalent large diameter wire. In a folded dipole, there are shunt transmission line stubs across the feedpoint which you don't have with an unfolded dipole, and some people think these impact the bandwidth. They do, but only to a very minor extent.

In a real folded dipole, the presence of the dielectric might modify the bandwidth slightly, but not much.

Andy,
What you've described is a typical 'passive' repeater antenna,
they've been around for a long time. Under certain conditions,
they may be the 'best' alternative to not having an antenna.
But,
you seldom see those conditions, and not in the situation you've
described. It works, but not very well.

Rob -

I do not know what "Doc" is referring to.
HeathKit support and repair work is still readily available, from a number of sources (I am not aware of a Canadian firm, however).

Manuals for many kits are still available directly from HeathKit

Heathkit (which is still in business for educational systems,etc.) refers past kit owners to:

RTO Electronics In Benton Harbor, MI (has extensive HeathKit parts collection)
http://www.rtoham.com/

Here is the KB9JJA's HeathKit web site:
http://members.accessus.net/~dwentz/kb9jja/heathkit/

NC Total Electronics has a number of parts:
http://www.nctotalelectronics.com/

Here is the HeathKit board for equipment owners:
http://members3.boardhost.com/heath32a/

The Heathkit Shop
http://www.theheathkitshop.com/

Reference Page
http://www.heathkits.com/new_collection.html

Heathkit parts (New Old Stock - NOS) .. you have to inquire he does not have the thousands of boxes
inventoried for the Internet.
http://www.multi-volti.com/

There are others, but this is a "start"

Also, do a Goggle search (hey its the Internet and search engines are the card catalogs)
on "Heathkit" and "repair" you should get a number of other web pages

How about a Comet GP-15 Vertical for 6m/2m/440 and a triplexer.?
That way you could use all three bands simutaneously.
As far as horizontal for 6, MFJ makes a 2m/6m center-fed antenna that
could be installed horizontal or you could make a simple dipole.
You might be surpirsed how well the vertical works on 6 SSB, quite a
few 6m SSB' ers are vertical.

Can anyone tell me anything about this discone antenna? >Supposedly it will work everything from 50 mhz - 1.2 gigs... any input is >appretiated.

The Diamond discone, with its vertiacl radiator, will work on 6m. As noted in earlier posts, keeping things together can be a problem -- I used thread sealer on mine, and have had no problems.

While discone antennas are wideband, you don't get something for nothing. The take-off angle increases with frequency. When you get to the upper frequency limits of the antenna, the main lobes are pretty high up. Do a google search on discones, or look at the RSGB VHF=UHF manual. The RSGB book has the design equations for discones (I've also seen these on a few web sites).

If you're going to use it at higher frequencies (anything higher than 2 meters) don't skimp on the feedline -- RG-8 won't cut it, especially if you're looking at 50 feet or more. Use something such as 9913 (a pain to work with), or Times Microwave LM400.

Have fun!

Passive repeaters for use in cars have been sold to naive cellular phone users for years. Some years ago, I ran some tests at a certified lab on some cellular phone passive repeaters, and verified that they make a hardly perceptible difference when used in a typical sedan. (There was a very slight movement of a pattern null or two, but a much larger change was made by adjusting the position of the front passenger seat.) The fact is that much more energy escaped through the windows than was intercepted by the passive repeater's internal antenna. At 2 meters the wavelength is several times longer, so the windows won't be quite as transparent. But I still doubt that an objective test would show any significant help from a passive repeater in a typical car at 2 meters. (There were, incidentally, some glowing testimonials attesting to the effectiveness of the cell phone passive repeater.) A passive repeater would surely help in a sealed metal container like a semi trailer, and in some cases a metal building. If I were making a passive repeater, though, I sure wouldn't use a rubber ducky for either antenna. The loss would likely negate whatever benefit the passive repeater might otherwise provide.

Bob, you need to remove the battery and the front cover to replace the antenna. They usually use a small hex head screw to take apart the case. Not sure which Nokia you have but I have changed a few of the 51xx/61xx series and this is how they are assembled.

Thats obviously a 'staged' photo by a third party. I see 3 pair of
wire-cutters/small pliers and no wire, a $3 soldering iron, an empty
'Third Hand' PCB holder, three dudes (only one of which has been to a
hair stylist) trying to look serious about the latest Mattel Kid-Compu
(eating batteries 3 inches away from an AC outlet) and no sign of an
antenna..or even a beer at 10:30.
They say pictures tell 1000 words.

> SWR measurements,
==========
There may be a problem for the operator but there is no problem for the transmitter. Insofar as the transmitter is concerned the SWR meter ALWAYS gives the correct answer.

Common mode invariably exists to some larger or smaller extent. Twiddling the tuner to give SWR=1:1 does not mean there is no common mode. But the transmitter is very happy.

Obsession with SWR is a defect of an operator's mental processes. And of authors of magazine articles and technical editors. It seldom bothers the transmitter.

Help yourself to a Christmas present.

Sure, I'd prefer at least 3-4 normally. But he only needs one to have
an efficient antenna as long as the antenna is elevated a bit.
Preferably a 1/2 wave or more. But the antenna acts more like a
vertidipole instead of a vertical. The pattern will be egg shaped with
gain towards the wire. With two radials the pattern is almost a
perfect circle. Just a very slight squash to it. Not much different
than 4. This kind of applies to inv L's compared to T verticals. A T
has a much cleaner vertical pattern. It's almost just like a 1/4 wave.
Has an overhead null, etc.
Won't have an overhead null on an inv L. MK

4385. Re: New concept for mobile antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-22 04:37:36 UTC
From: arm@helix.nih.gov
Message-ID: <k6UU7.434$%D6.550789@mencken.net.nih.gov>
Source record: 152335

I did not expect the overall concept to be new, but I was interested
to learn that the technique had been tried in cars already.

Thanks to those who provided the more detailed responses.

Considering how poorly a typical HT (with rubber duck) inside
a car performs, it would not take much efficiency to greatly
improve the signal. My experience is that a 100mw rig outside
the car works better than a 1w HT inside the car at 2 meters.
So I thought the passive antenna system would be a substantial
improvement.

Would you speculate the failure is due to multipath inside the car?
That is, the interior antenna can too easily find a null? What
about a spatial diversity passive repeater (e.g. two passive
repeaters).

I've noticed a SWR of 5 or higher makes all the panel lights blink and pops
the breaker on the power supply at extended transmits.

Yes Jim, I confess to a little exaggeration at times. But I think you get
the point about obsessions.

If it gets too irritating being plunged into darkness in the middle of a
rag-chew you could try shoving a wedge or something into the circuit
breaker. Or just stop shouting into the mike.

Source record: 152339

I think the problem is that the inside antenna intercepts only a tiny fraction coming out of your transmitter.

Here's a better idea: Connect a cable directly from your radio to the outside antenna. Then all the power from your transmitter (except for a little cable loss) ends up being radiated from the outside antenna. And if you use the right kind of connector, you can connect and disconnect the cable from your radio quickly and easily.

Hi Jim,

Classic evidence of Common Mode currents returning down the outer
shield of your feedline. Choke the drivepoint as I described. You
can confirm (or reject) this with the extremely simple test I already
offered.

The Diamond disconne is very ticklish in this area also. It is very dependent upon surrounding objects as to whether a good enough match can be obtained. It would not be my first choice for a six meter antenna. I have an MFJ six meter tuner that I use with the Diamond disconne and the Austin Suburban antennas. They are good enough for local repeater work.

The Cushcraft AR-6 or the Diamond six meter monoband vertical are better. Obviously, the Diamond is the top of the line, but is approximately twice as expensive as the Cushcraft - but with twice the performance.

4396. I want to build a terminated dipole for HF

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-22 12:47:45 UTC
From: Empty Horn <emptyhorn@hotmail.com>
Message-ID: <a01vdg$67e$1@knossos.btinternet.com>
Source record: 152344

First, if you're thinking of replying by telling me not to, just move along to the next posting, please.

Now, then. Please would someone advise me as to the validity of this setup for HF:

A 12:1 (600:50) balun at the centre;
A couple of very long legs, each terminated by an appropriately-valued 300 ohm resistor.

The 12:1 step-up is a guess - is there a better ratio and where on the web might I find a schematic for the optimum balun?

Thanks for any help. Curses for any obstruction. (Call me cynical, but I can't helping thinking that my opening line won't have had the filtering effect I intended.)

M

4397. Inverted L for 160 questions

Newsgroup: rec.radio.amateur.antenna

4400. Re: New concept for mobile antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-22 15:22:03 UTC
From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3c24a88c_2@news1.prserv.net>
Source record: 152349

Andy:

One of the 'reputable' antenna manufacturers actually offered this system for sale back in the late 80s early 90s time frame (for cell phones). And maybe it was the company for whom Roy made the measurements, because they pulled it from the market with apologies after some properly instrumented tests were performed. I think it was ----- no, I suspect they learned their lesson and should be left in peace.

To kind of paraphrase what Roy said, the problem is that the metallic structure of the auto cab is a leaky shield. Not good enough to keep all the signal out (or in), but good enough to produce significant additional path loss. I think diffraction may be more of a contributor than multipath, although I suppose it could be argued they are both manifestations of the same problem.

You might try another thing, which is very revealing. Use a quarter wave antenna instead of the rubber duck. The added efficiency is obvious. Just don't try it with a passenger present. It's amazing how long 19" is inside an automobile interior. On 440, the quarter wave is usable, and still works better than the duckie. Another approach is to find a 1957/8 T-Bird with the optional fiberglass top.

Hi Bart,

Tell more about this effective height of a small loop. Your formula
would leave us with Metersï¿½ and not Meters, a linear measure.

Consider how much of the signal an internal receiving antenna
would soak up. If it was one degree wide, it would soak up
1/360 of the signal.

Hi All,

The origins of English are found in the both the nordic and romance
languages. That is, English borrows heavily from German and French.
There is, of course, a considerable amount of Latin (whose roots are
found in India's sanskrit).

>PLAIN ORDINARY commonsense ENGLISH

From the Oxford English Dictionary we find:
Plain - Old French, plaign, or from French plein, or Latin planum;
Ordinary - early Old French ordinaire or Latin ordinarious;
Commonsense - Greek, or Latin sensus communis
English - Old Teutonic anglisko

>WHAt other society in the world IMPORTS another
>countries language to replace it's OWN???????HOW pathetic!

Indeed....
What - Old teutonic hwat (English juggles spelling too)
Other - Dutch and German ander
Society - Old French societe
In - Old High German, Teutonic
The - Sanskrit tat
World - Teutonic weorold
Imports - Latin importare
Another - see Other, above (English also compounds like german)

Country's (misspelled above) - Old French contrï¿½e
Language - French langage and Latin lingua
To - Old Teutonic ta or Lithuanian da
Replace - Bingo! No derivation shown.
its (misspelled above) - Bingo! however original English was hit
Own - Old Teutonic aigano
How - Old Norse haug
Pathetic - Late Latin patheticus

Even the puffery of being Anglo-Saxon relates to the German tribes of Angles, Saxons and Jutes. Hence our correspondent above barely qualifies as English literate (at 10% for original English content with points lost for spelling throughout).

If you want correspondence in original English, from "Cï¿½dmon's Hymn"
Nu sculon herigean heofonrices Weard
Meotodes meahte and his modgeï¿½anc
weore Wuldor-Fï¿½der swa he wundra gehwï¿½
ece Drihten or onstealede
He ï¿½rest sceop ielda nearnum
heofon to hrofe halig Scyppend
Da middangeard moncynnes Weard
ece Drihten ï¿½fter teode
firum foldan Frea aelmihtig

The split in the stanzas is known as a Cï¿½sura, a pacing device, or pause during recitation.

Perhaps this little piece offers a compelling answer to that pining
>WHAt other society in the world IMPORTS another
>countries language to replace it's OWN???????HOW pathetic!
because the word "modgeï¿½anc" means mindset. :-O

Hi OM,

The olde fashion way, reading and typing. All references are within 6 feet of me. "Cï¿½dmon's Hymn" was courtesy of "The Norton Anthology of English Literature."

One of the pleasures of English found before Shaksper is that so much of it written seems like gibberish - until you hear it. With Shaksper's work, the language grew enormously (but his work was actually written in an old dialect that was not spoken during his time). Where the educated citizen has a vocabulary of say 10,000 words, his works reveal nearly three times that.

The conceit of Shaksper is a product of having just seen "The Beard Of Avon" two nights ago. [No that wasn't a typo, it is a comic stage play of the "authorship problem."]

Source record: 152365

Nospam,
The 'best' length is as long as you can possibly make it.
The
'usual' way of doing it is to get as much height as possible,
then
have as much wire horizontally to make the total something on the
order of 120 feet. Ground for an inverted 'L' is important, the
'better' the ground, the better the thing works. A couple of
radials
or a couple of ground rods are seldom enough, and the more metal
in the ground, the better (when you get to the point of saying,
"forget it!", you almost have enough ground). Probably the most
common method of feeding the antenna is by coax to a matching
net-
work at the base of the 'L'. If you have a tuner, the matching
network at the base of the antenna isn't necessary, or you can
feed it with ladderline is you want.
This isn't a 'definitive' answer, but it should give you
enough
of an idea to get started...
'Doc

I realize that Cecil was just giving an example, but it appears to perpetuate the misconception that the physical size of an antenna determines how much signal it'll intercept. The amount of signal "captured" by an infinitesimally short dipole from a given direction is very nearly as much (just 0.45 dB less) than the amount "captured" by a half wavelength dipole. (Most actual very short dipoles, however, will dissipate most of the intercepted energy as heat due to conductor losses.) Making a dipole out of wire that's twice the diameter doubles its surface area but has no significant effect on the amount of signal intercepted.

But even so, an interior antenna will intercept only a small fraction of the power radiated by the HT, as Cecil says.

Hi,
no I am sorry, there is NO any relationship with fractal antennas.
The eh antenna is not resonant on any part of it.
Crazy George did some confusion...he was referring to CFA story....
the eh antenna was presented to the world here in Italy 4 months ago during
a ham fair.
just for clarity,

What I was mentally picturing is the doughnut of radiation with an
antenna slice along one degree of the doughnut. The other 359 degrees
of the doughnut is not incident upon the antenna.

Oh it gets worse. Pretty soon we will hear from the Latin scholar
objecting to ending sentences with prepositions. This resulted in I
believe Shaw and possibly used by Churchill replying to a critic with,
"That's the sort of nonsense up with which I will not put."

> >physical height.
> >
> >The concept of effective height is not limited to linear antennas. The
> >effective height of a small loop antenna equals 2 * pi * N * A where:

Should be:

heff = 2 * pi * N * A / lambda where:

N is the number of turns
A is area (m^2)
lambda is the wavelength in the medium

> >Doubling the diameter (quadrupling the area) will increase the output
> >voltage by a factor of four rather than two as might be expected from a
> >simple dimensional analysis.

> Tell more about this effective height of a small loop. Your formula
> would leave us with Metersï¿½ and not Meters, a linear measure.

My original post was sloppy and I neglected a scale factor of 1/lambda.
The point is that in the case of a small loop, the transduction gain
increases with the physical dimension squared.

The term 'effective height' is an abstract system engineering term which
is defined as the transduction gain relating the open circuit voltage at
an antenna's output terminals (or antenna and preamplifier) to the
electric field being sensed.

Small loop antennas work by direct application of Faraday's law of
induction.

The terminal voltage is equal to the time rate of change of magnetic
flux encircled by the loop, multiplied by the number of turns in the
loop. Instead of directly sensing the linear electric field, the loop
senses the magnetic flux enclosed by the loop, which is related to the
circulation of the electric field via Maxwell's curl equation for the
electric field.

In time harmonic form: curl E = -j * omega * mu * H where

E = electric field (v/m)
j = sqrt(-1)
omega = angular frequency (radians/sec)
mu = permeability of medium (H/m)
H = magnetic field (A/m)

Assuming the field (and permeability) are reasonably uniform throughout
the loop, the curl equation can be integrated:

V = -j * omega * mu * H * A where

A is the area of the loop (m^2)
V is the induced voltage (v) for a single turn.
H is now the _average_ value of the magnetic field enclosed by the loop.

Therefore the loop is actually a different type of transducer than the
short vertical. It 'measures' magnetic, not electric field. A small loop
transduces the time rate of change of magnetic flux to voltage. In
order to use a small loop to sense electric field strength, a
relationship between E and H must be obtained which allows some function
of E to be substituted for H in the above equation. In general, no
unique relationship exists but for the _special case_ of a propagating
electromagnetic plane wave,

H = E / sqrt(mu / epsilon) where

epsilon = the permittivity of the medium (F/m)

The ratio E/H = sqrt(mu/epsilon) is often referred to as the intrinsic
impedance of the medium and serves a similar role in free space
propagation analysis as the characteristic impedance of a transmission

line (sqrt(L/C)) does for transmission line analysis.

The transducer equation, constrained by the assumptions stated earlier is now:

V = -j * omega * mu * E / sqrt(mu / epsilon)

Simplifying and introducing the fact that the speed of an electromagnetic wave propagating in the medium is:

c = 1/sqrt(mu * epsilon)

V = -j * A * E * (omega / c)

But (omega / c) = 2 * pi / lambda where

lambda is the wavelength (m)

So:

V/E = -j * A * 2 * pi / lambda for a small single turn loop in a uniform field and homogenous medium.

For a multiturn loop:

V/E = -j * 2 * pi * N * A / lambda

Note this derivation only applies to the plane wave case in homogenous media where the relationship between the electric and magnetic fields has the relationship
E/H = sqrt(mu/epsilon). This relationship does not hold in the near field of an antenna system or interference source.

Hello All,

I have been in search of the design instructions for the
tiny "2m Pounder" Beam.

I have not been successfull in locating this.

Does anyone have a scanned copy of the initial
design instructions from the ARRL handbook?

Any help is greatly appreciated!

AMATEUR RADIO NEWSLINE(tm) REPORT #1271 - DEC 21, 2001

Amateur Radio Newsline report number 1271 with a release date of Friday, December 21st, 2001 to follow in 5-4-3-2-1.

The following is a Q-S-T. A national ham radio society is asked to train new hams for government service. This story is first on this weeks Amateur Radio Newsline report number 1271 coming your way right now.

(Billboard Cart Here)

**

THE EDUCATION SCENE: HAM TRAINING LEADS TO SA GOVERNMENT JOBS

A government agency has asked a national ham radio society to help train new hams. The reason. careers with that agency. Its happened in South Africa as we hear from Q-News Graham Kemp, VK4BB:

--

In South Africa, their Department of Communications contacted the SARL with the request to train seventeen post graduate students as amateur radio operators. These students had already qualified in different fields, some technical and some in the Information Technology fields. There were nine ladies and eight men. From next year they will be employed by the Department of Communications, and the idea was to give them some experience in the field of radio communications.

Training was done by Henry Chamberlain, ZS1AAZ, over a period of one full month. In addition to lectures, the students could see practical demonstrations of amateur radio and they spent one period building and testing a Morse Code practice oscillator. They also visited ZS1AAZ's home shack. The seventeen students had already proved their ability by passing their previous studies successfully. It was therefore no surprise that they ALL passed the amateur examination.

For the Amateur Radio Newsline, I’m Graham Kemp. VK4BB, of Q-News.

--

The seventeen will be assigned specific jobs with the South African Department of Communications in early 2002. (SARL, Q-News)

**

SPECTRUM SHARING: FCC SAYS YES TO HIGHER POWER UNLICENSED TRANSMITTERS AT 2.4 GHZ

The FCC has approved issued new rules permitting certain unlicensed Part 15 devices operating between 2405 and 2450 MHz to use higher power, but under significant restrictions. The band is allocated to amateurs on a co-secondary basis. Amateur Radio Newsline's Norm Seeley, KI7UP, takes a look at the FCC action:

--
According to the C-Q Magazine website, the decision was adopted on December 11Th. In it, the FCC approved a petition by Sierra Digital Communications, Inc. to permit unlicensed fixed point-to-point transmitters in the band to operate at field strengths of up to 2500 millivolts per meter. This is a tenfold increase over past power limitations.

Sierra Digital Communications manufactures and sells equipment for wireless data communications, including high-speed wireless computer networks and Internet links. The ARRL had opposed Sierra's petition on the basis of increased risk of interference to amateur and amateur satellite operations. This is because the downlink from the AO-40 satellite is in the 24 GHz band.

But the FCC said it believed the restrictions it is imposing on the higher-power transmitters will provide sufficient protection to other users. This includes industrial/scientific/medical equipment, radar and Earth exploration satellites, in addition to amateur radio. The new rules require highly directional antennas and high frequency stability of transmitters.

For the Amateur Radio Newsline, I'm Norm Seeley, KI7UP.

--

In its decision, the FCC singled out an ARRL comment where the League clamed that Part 15 devices are permitted by the Communications Act of 1934 only where they have no interference potential to licensed services. The Commission called the League's interpretation of the law overly conservative. It said that its rulings to date appropriately provide a means for allowing unlicensed devices to share spectrum with licensed services with little risk of interference and adequate protection to licensed service. (CQ)

**

HAM RADIO AND THE WAR: MARS ON THE AIR FROM THE WAR ON TERROR

Ham radio is making it possible for those fighting the war against terrorism to phone home. This as the ARRL Letter announces that Army Special Forces on duty in Islamabad, Pakistan, and in other undisclosed locations have begun keeping in touch with home via MARS -- the Military Affiliate Radio System.

Phone patches provided by the Military Affiliate Radio System make it possible for troops to call their families in the US from areas where commercial communications channels are not available. Amateur Radio operators enrolled in MARS provide the connection between the Military Affiliate Radio System stations deployed overseas and the telephone system back home.

During the Vietnam War, phone patches were a major source of comfort to families and service members alike. MARS also responded during Operation Desert Storm. (ARRL)

**

BREAK 1

Wishing you a Happy Holiday from the United States of America, we are the Amateur Radio Newsline, heard on bulletin stations around the world, including the Great South Bay Amateur Radio Club repeater, W2GSB, serving West Babylon New York.

(5 Sec Pause Here)

**

HAM RADIO AND THE WAR: GODDARD ARC FEELS THE PINCH

The Goddard Amateur Radio Club says that it has been having serious problems with manpower lately and the war on terrorism is partly to blame. This is because new security restrictions imposed after September 11th require all visitors to Goddard to be escorted by a badged employee at all times.

According to Dan Schultz, N8FGV writing to the Amsat Bulletin Board, the clubs WA3NAN ham shack is located on government property we are bound by the new restrictions. This says Schultz makes it much harder to bring in control operators who are not Goddard employees. As a result, WA3NAN which for years has been the primary rebroadcaster of shuttle communications on the ham bands is not there as often as it would like to be.

Schultz also notes that the Goddard Amateur Radio Club currently has no president because no one has stepped forward to accept the job. The position of Shuttle Retransmission Director is also vacant, this is the person who makes the phone calls to get operators lined up to pull shifts at the retransmission facility.

Schultz says that the long term technical solution will be to automate the station with remote controls and telemetry for the transmitters so that the retransmission operator can operate from his home. But adds N8FGV, but that is still a little ways off in the future. As a result, WA3NAN is not there as much as it used to be. (AMSAT-BB)

**

AMERICA AT WAR: NEW HOMELAND TERRORIST ALERT SYSTEM PROPOSED

Homeland security chief Tom Ridge is considering a multistage system for terrorism alerts. Ridge is also weighing how to reimburse states for the costs of increased security since the terror attacks.

Since the September 11th terrorist attacks on New York and Washington, Ridge has issued three general warnings. None of the alerts identified specific targets.

Now, according to news reports, Ridge will propose a four-stage Threat Alert Network similar to the military's DEFCON'' system. DEFCON alerts military personnel to the seriousness of a threat. A private sector version would be aimed at helping state and local law enforcement personnel determine the level to react to a Federal government issued terror warning.

The proposal came to light after California Governor Gray Davis met with Ridge about a week and a half ago. Davis told Ridge he had proposed such a similar system for California, and said Ridge had asked him to wait pending a national model. Ridge told Davis that he hopes to unveil the national system by January 15th of 2002. Whether or not ham radio will play any part in such an alert system is not known as we go to air. (Published news reports)

**

AMERICA AT WAR: CONFERENCE HELD ON ALERTING THE PUBLIC

Still in there area of alerting the public, more than 120 leaders from the emergency warning community met November 30th and unanimously called for the creation of a public-private partnership. This, aimed at improving the delivery of timely and accurate emergency information to people at risk. Don Wilbanks, KC5MFA reports:

--

The group came together at a special conference arranged by the National Warning Organizing Committee. This is a group of emergency warning advocates representing the public and private sectors.

Those attending included federal, state and local government officials, not-for-profit organizations, and representatives from the private sector. And in the end the group has tasked itself to improve the delivery of warnings and emergency information to the public. This, through better education, research, standards creation and policy recommendations.

The Committee Chairman is David Liebersbach, Director of the Alaska Division of Emergency Services. He has appointed Peter Ward, formerly of the U.S. Geological Survey and chair of a White House-appointed working group on natural disaster information systems, to head up a committee to determine the new organization's structure and governance. Ward also serves as the new organization's spokesman. More news on the work of this committee as information is released.

For the Amateur Radio Newsline, Don Wilbanks, KC5MFA, in New Orleans.

--

The conference was hosted by The MITRE Corporation in McLean, Va. MITRE is a not-for-profit national technology resource that provides systems engineering, research and development, and information technology support to the government. (MITRE)

**

HAM RADIO AND EDUCATION: HAM RADIO MASS BALLOON LAUNCH

The Timberlane Regional High School, in Plaistow New Hampshire will be taking part in a high altitude experiment next spring. This with an announcement that the Coordinated Algebra II and Physics classes taught by Lorainne Mascioli, N1VYQ, and Lou Broad, N1RCA, are planning thier third year of ham radio and high altitude balloons in May of 2002.

Six student teams will attempt to launch their balloons at the Hosstraders Ham Fest at the Hopkington Fair Grounds in New Hampshire. Each team is responsible for design, construction, and operation of their system. Each balloon will carry a GPS receiver, a packet reporting system and several experimental payloads. This could include cameras, video, amateur television and cross band repeaters. At maximum altitude such systems will have a range of 300 miles and should easily cover all of New England and more.

The class has grown to 34 students and they are planning to launch six balloons in a two day period! This could make it a record breaking event in both ham radio and high altitude ballooning. For more information check out the CAPSAT Website located in cyberspace at
http://www.mv.com/ipusers/llb/capsat.html (Via Internet)

**

HAM RADIO SPOTLIGHTED IN POUGHKEEPSIE JOURNAL

New York’s Poughkeepsie Journal has highlighted ham radio in a December 6th front page article. The piece focused on the public service aspects ham radio with quotes and pictures.

According to Andrew Schmidt, N2FTR, who is an ARRL Assistant Director in the League’s Hudson Division, many Poughkeepsie area local hams spent time at Ground Zero or at the Red Cross centers in the greater NYC area following the September 12th terrorist attacks. Andrew says that their work is well highlighted in the article. The link is:
http://www.poughkeepsiejournal.com/thursday/community/stories/co120601s12.
shtml. (Via Internet)

**

A SPECIAL AM EVENT: THE HEAVY METAL RALLYE

This is Paul Courson WA3VJB with news of an operating event Saturday night, December 22nd. It's the Heavy Metal Rally, featuring big iron, vacuum tubes, and the warm and inviting sound of AM on the shortwave ham bands.

Starting around local sunset listen for rigs in the 250 watt or 250 pound category to populate AM gathering points on 160, 75 and 40 meters.

Jim, W8MAQ was testing HIS 1947 Collins 300-G a few days ahead of the Heavy Metal Rally. The retired broadcast transmitter re-tuned to 75 meters sounded like this:

In-Q: it's been great to get on... 300-G..
Out-Q: forward to that

--

Prizes include a trophy, pictured as a posting on QRZ.com, for the best sounding station.

Last year more than a hundred stations took part -- and the winner was Mike, WN3B, on a Gates 250-C. He gave Jim an audio report the other night:

--
In-Q: It's got more highs....
Out-Q: Shure 55
--

The Heavy Metal Rally is sponsored by Electric Radio, a magazine featuring vintage ham radio, and published by Barry N6CSW. The event was pioneered by Bill, KD0HG of Colorado, a broadcast engineer with a knack for big homebrew rigs that sound great.

Frequencies and a website are listed on the news page of QRZ.com.
Paul Courson, WA3VJB, Annapolis Maryland.

**

HAM RADIO HISTORY: COLLINS RADIO CENTER NOW OPEN

The new Collins Radio Center which is the headquarters for the Collins Radio Association is now officially open for guests and visitors. Located near Johnstown, Pennsylvania, the Collins Radio Center includes a representative collection of Collins radio equipment, from the 1930's to the present. There are other classic and antique radios on display as well. More information is on the web at www.collinsra.com. (Collins RA Press release)

**

HAM RADIO BUSINESS: CITY ELECTRONICS - RIP

Alex Stalinsky, WA5UHT, who owns City Electronics, a small parts outlet in Houston for almost 50 years, has decided to call it quits. According to Chris Boone, WB5ITT, this place was one of the main sources of parts, components in Houston long before the likes of Mouser and Digikey took off in mail order sales.

Chris tell Amateur Radio Newsline that he bought many parts from City Electronics in his early days of repeater building. In fact, Chris says his mother claimed that he owned half of the local Radio Shack but she was wrong. It was really like he was a part of City Electronics as were many other young Houston area hams and Chris tells Amateur Radio Newsline, it will be missed. (WB5ITT)

**

EMERGING TECHNOLOGY: INTELS NEW WARP SPEED CHIP

In another step toward faster computers, Intel Corp. has developed two new technologies that will help the tiny transistors inside microprocessors run cooler, use less power and operate more efficiently. The new designs

complement several recent breakthroughs in building minuscule transistors that form the basis of all modern computing as they switch on and off billions of times a second. Earlier this year, Intel unveiled transistors just 20 nanometers wide. Today's Pentium 4 has 42 million transistors, each about 180 nanometers. For reference, a manometer is about 10,000 times narrower than a human hair. (Intel)

**

EMERGING TECHNOLOGY: DTV ROLLOUT UPDATE

Roughly two-thirds of commercial television stations plan to broadcast a digital signal by a federal government deadline of May 1, 2002. This, according to the National Association of Broadcasters.

In a report to the Federal Communications Commission, the industry group said that many of those that won't make the deadline are waiting for equipment to be delivered and expect to have digital broadcasts on the air in the months afterward. But some stations in smaller markets are having a hard time paying for the upgrade, the association says.

Right now, most home television sets in use receive only analog signals. But congress has mandated that broadcasters must give up their analog channels to the government by 2006. As a result, there are concerns that consumers won't have made the costly upgrade to televisions that can receive digital signals by that date. (Broadcasting Daily)

**

HAM RADIO IN SPACE: EXPEDITION 4 CREW NOW ON THE ISS

An all ham crew is now in charge of the International Space Station and will be for the next six months.

Three astronauts and cosmonauts now running the ISS. They are Russian Commander Yuri Onufrienko, RK3DUO, along with American Flight Engineers Dan Bursch, KD5PNU, and Carl Walz, KC5TIE. They make up what is called the Expedition 4 crew and all three are expected to be on the air regularly for school contacts and possible open QSO times made available to talk with hams worldwide, as time permits.

The Expedition 3 crew comprised of United States Commander Frank Culbertson, KD5OPQ, along with Russian Flight Specialists Mikhal Tyurin and Vladimir Dezhurov is now back on good old Mother Earth. They returned on Monday, December the 17th aboard the space shuttle Endeavour. (AMSAT-NA, ARISS)

**

HAM RADIO IN SPACE: EDUCATIONAL ASSISTANCE FROM VK5ZAI

Attention educators. If you are thinking about teaching the International Space Station, here is a bit of assistance.

Tony Hutchison, VK5ZAI has updated his web pages with links to help schools in obtaining educational programs associated with the I-S-S and space science in

general. Hutchison says that this should be of interest students and teachers alike especially if they are contemplating applying for a ham radio contact with the astronauts on the station.

Hutchison is the Australian ARISS Coordinator. His website in cyberspace at www.electric-web.org (VK5ZAI)

**

SPACE AND SCIENCE: CHINA ON THE BRINK

Space Daily reports that China is getting ready to launch its third unmanned spaceship. This, to pave the way for sending that nations first astronaut into space sometime next year. China is reportedly also in final testing and preparation to launch a new satellite dedicated to study ocean colors and related phenomena. (Space Dailey)

**

DX

In DX, 9V1YC reports that he and eleven other hams will be activating South Georgia and South Sandwich Islands in January and February of 2002. The operation will be strictly on the high frequency bands. Exact dates, call signs and QSL managers are not being made public until the group is actually on the air. The New Zealand registered vessel "Braveheart" of ZL9CI fame will be supporting this team for the entire 30 day trip. (RSGB)

A bit higher in frequency, Jeff Klein, K1TEO reports that December 6th was another great D-X day on the 6 meter band. Jeff who lives in Connecticut says over the VHFReflector that the band was open for a solid two hours beginning at 7:30 am local. And talk about D-X. On his very first C-Q he landed HB9QQ who was operating portable HB0. Even better, Jeff says that the fifth caller was 4X1RF. (VHF Reflector)

Over in Great Britain hams are actually D-Xing for charity. Jeramy Boot G4NJH, reports from Nottingham in the U-K.

--

Every year in September, the British Wireless Fund for the Blind -- a registered charity - organises a fund-raising event in which amateur radio clubs and individuals are sponsored for the number and distance of the contacts that they make. As of the 11th of December, the British Wireless for the Blind Fund reported that 'Transmission 2001' had raised £6681.48, with more coming in every day. They say that they hope the final total will reach £7000. The charity offers prizes to the club and individual raising the greatest amounts.

This year the Cray Valley Radio Society operating as GB2FB and taking part for the first time, won the prizes for the club raising the most money and for making the most contacts. Robert Guscott, M5GUS, operating as GB0WB, won the prize for the leading individual.

Jeramy Boot, G4NJH.

--

The bottom line. This is another way that hams can not only enjoy their hobby, but can help others at the same time. (G4NJH)

**

THAT FINAL ITEM: A HAM RADIO CHRISTMAS STORY

And finally this week, the story that we wait all year to tell you. Its the ongoing story of hams who care about hospitalized children and what they do to bring a bit of holiday cheer to those kids who cannot make it to the mall to spend a few moments with old Saint Nick. Here’s Amateur Radio Newsline’s Joe Moell, K0OV:

--

As most hams know, propagation is very good this time of year. It's so good that it's easy to make contact with the North Pole. Many clubs around the country are taking advantage of these propagation conditions to set up QSOs with a very special North Pole station. They're making these contacts from hospitals and rehabilitation centers, and they sound like this:

--
Santa and Kids Audio Here
--

That's what the North Pole Network sounds like in southern California, where it's celebrating its 25th anniversary at Childrens Hospital of Orange County. In the past few days, I've heard from other clubs in the North Pole Network, including the AkSarBen ARC in Omaha and the Southwest Missouri ARC in Springfield. And YOUR club could bring holiday joy to hospital patients. There's a how-to article on the subject, with a dozen suggestions for your best North Pole Network ever, currently running on ARRL's Web site. That's arrl.org, of course. And there's even more about North Pole Network in southern California, plus lots of photos showing a quarter century of holiday fun, at the Hospital Disaster Support Communications System Web site, www.hdscs.org. Check it out, and start planning for your own North Pole Network joy.

4428. Hy-Gain AV-640 vs DX-77A

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-23 04:02:50 UTC
From: Randy Hoops <RandyHoops@Home.com>
Message-ID: <ccla2ukp2g83lmjdl1e8tsdvhln3jc5cpu@4ax.com>
Source record: 152380

I'm thinking about getting a vertical antenna and would like to hear a comparison of the AV-640 and the DX-77A. Hy-Gain praises the slightly cheaper AV-640 as the "best built, best performing and best priced multiband vertical available today". Since they also make the DX-77A which is $70 or so more expansive, this seems like a no-brainer. The DX-77A has been around a few years, and the AV-640 is newer. Is there any reason I've want the DX-77A? Do you think other verticals are better for any reason? (Of course we all know a Hy-Tower is better at twice the price).

Not quite gov'nor

I was merely re- iterating the level of intelligence by paraphrasing(if you know what the word means) which i think the CRETIN who insulted me possesses.
I was demonstrating how i think the CRETIN speaks,judging by the level of illiteracy which he exudes.You and he both clearly miss the point of my message.

You don't impress me at all by misquoting what i originally said,which is out of context to the original message.ANY fool(you as an example)can cut and paste.You are not clever.

Better luck next time "pal".

Patrick

Francesco,
I am afraid you will find no scientific tests of the 'EH'
antenna
that are not compromised in some way. All of the testing done to
date
have faults. It can be compared to the 'CFA' antenna in this
regard.
'Doc / W5LZ

Languages evolve. Meanings of words change while new words emerge. (Remember when "gay" didn't mean homosexual?) And don't give me shit about our language not being English. The French spoken in Canada is different from that in France, but it's still called French. Same goes for Mexico and Spain with the Spanish Language. As long as people communicate their thoughts and understand each other, why should you or anyone else criticize? Get a clue, you stupid-arse wanker!

4437. Re: CB "J" pole

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-23 07:41:25 UTC
From: Terry <terry@mindstate.nospam.com>
Message-ID: <3c258e16@news.planetc.com>
Source record: 152388

I constructed my 10 Meter J-Pole out of a 40 foot mast. The tuning stub is made out of 3/8" copper pipe. I have it guyed off with braided polyester cables. I do not know how local performance is because I have only worked one local station. DX performance is -GREAT-. With only 20 Watts, I can work anyone I hear and even break through pile-ups.

The neat thing about doing it this way is you don't have to mount the j-pole. It took two friends to raise the antenna though.

Granted, it's not being plugged as paranormal, but the latest line fully qualifies the inventor for a million dollars in cash secured by the James Randi Educational Foundation. All he has to do is agree to a controlled test whereby his device can show that it's capable of "accelerating plant growth". Test to be verified by an independent party. Read up on: http://www.randi.org/

How about it, Stefano? Make them magic beanstalks grow, eh?

4439. Re: Anttron 8010-B ? ANY GOOD?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-23 08:15:22 UTC
From: 'Doc <w5lz@icok.net>
Message-ID: <3C259284.C74B3564@icok.net>
Source record: 152390

Chris,
I finally found the '8010-B', read the advertising, and
think for the price, you could probably make two or three
good all-band antennas that would work at ~least~ as well.
In other words, if you ground up the '8010-B', spread it
over your garden, wait three weeks, you'd have a bumper
crop! There's a very high 'nitrogen' content in Antron's
advertising, it's advisable to 'water' it down quite a bit...

From: 'Doc <w5lz@icok.net>
Message-ID: <3C25933A.2CE88C52@icok.net>
Source record: 152391

Wes,
As advised, try measuring the SWR of a dummy load. If
it comes out reasonably close to 1:1, then there isn't any
thing wrong with the meter. It's probably something your
not doing correctly in tuning the antennas.

Easy to do with the manuals. If you tackle it be sure to heat the coils a
LITTLE bit to free up the slugs before trying to turn them. (I've been
there)

> ideal length, grounding requirements, and best way to feed it from the
> shack?
> Thanks

The ideal length will be found when tuning it. IE: best match. I put one up 2-3 days ago. The impedance in theory will be low, but in the real world I've always been able to trim the antenna to get a decent match with no matching device. The more radials, grounding, the better. I've always fed them with coax to the base of the antenna. At this time, I have an inv L, and I also have a T vertical. Both are appx the same height as far as the vertical section. Both are working fairly well, but I have to give an edge to the T vertical. I think mainly because the max current point is up higher. My T antenna has a full 1/2 wl hat. So it's electrical height is about 1/4 wl plus 40 ft for the vertical section. The max current point is about at the top of the vertical section. I found I can feed both of them at the same time. :) Works pretty well. Also , I'm talking about a standard 1/4 wl inv L. You can also use extended inv L's. But you will need a series cap to match those. Usually, most people make an extended L about 190 ft long on 160m. The longer antenna has lower ground losses due the the max current point being raised off the ground,and more radiation at higher angles. It makes a good regional antenna. The 1/4 wl L is better for dx as it has more radiation at lower angles, and less overhead. The T vertical is even cleaner as far as the vertical pattern. It has a null overhead. MK

4447. Re: Does a quad have both V and H polarity?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-23 18:27:34 UTC
From: robert haviland <bobh@iag.net>
Message-ID: <3C262348.43A5750D@iag.net>
Source record: 152398

With a question, it's necessary to be precise. I assume by "quad" you mean a two or more element array of loops, square, and about 1 wavelength in perimeter, with the loops parallel and perpendicular to earth, and fed at the bottom.

For this antenna there is no vertical polarization component exactly at right angles to the plane of the loops if the antenna is symmetrical aboout the radiation axis. There is a small vertically polarized component at other angles, maximum in the plane of the loops. For a two element quad, the vertical component is about 20 bd below the main lobe.

Either would work. You could add a turn or two and it still would work
since it is fairly broadband.

Stefano,

I know that you have said that your current strategy is to avoid discussing theory and how/why the EH antenna works, but please take just a minute to explain a bit about your statement

"The eh antenna is not resonant on any part of it."

Taking this for what the words actually mean, at least in English, I get the impression that you are now saying that the EH is a frequency-independent structure, capable of operating on any frequency and presenting the same performance and characteristics on any frequency. That is usually a consequence of "not resonant," like a 50-ohm resistor dummy load.

I am not trying to be difficult, but from earlier postings by you and Ted Hart, I gathered that the tuning of the phasing networks was very important and critical and to me that suggested that the antenna did indeed operate as a resonant system that was highly and critically frequency dependent.

Please help me out here . . .and this is a different George! <:}

Thanks! And Happy Holidays!

72/73, George W5YR - the Yellow Rose of Texas QRP-L 1373 NETXQRP 6

>About 30 bucks for 500 ft of #12

Wow, HD prices are different in different parts of the country?
Hummmm.... interesting. I just got a 500' roll of #14 for $14+ last
week and the #12 was $21. Freehold NJ.
Yes, the nice thing about that HD wire that I use for inverted vees is
that when you drop the antenna to the ground the wire lays there like
a wet noodle. I literally coiled up my last antenna made out of
copperweld and threw it in the trash. Remember, IF the soft #14
should stretch a little, so what? Just trim it down and away you go
again (at least it doesn't SHRINK !!).

Dennis wrote:
"I agree that directionality will help a lot, but gain should not be a problem, and an outdoor antenna shouldn`t be needed because the reception outside (the house) is the same."

The more directionality an antenna has, the more gain it has. They are sides of the same coin.

Ghosts result from reflections. A directional antenna may improve the signal to ghost ratio. If AGC overloads, a loss pad may be used.

A yagi inside the house may be troubled by reflections from nearby conductors. Placed outside the house and well clear of surrounding conductors, household reflections should not cause ghosts.

Outside, the yagi may still be troubled by reflections from structures and topography. The more directional the antenna, the less ghosts. The antenna should be insensitive to the ghosts while receptive to the desired signal. A rotor may help null-out the ghosts in the TV picture.

Best regards, Richard Harrison, KB5WZI

??? So in order to prove your point, you dish out a totally unintelligible and illiterate post? Not to mention the drunken mumbling about "asians", "scandinavians", etc.

> You and he both clearly miss the point of my
> message.

That you dislike americanisms in the English language, yet are unable to write a coherent sentence in the language you're "protecting"?

> You don't impress me at all by misquoting what i originally said,which is
> out of context to the original message.ANY fool(you as an example)can cut
> and paste.You are not clever.

Any fool *may* be able to cut and paste, but that's one skill you apparently lack. Let me give you a few pointers: sentences begin with a capital letter. There is always a space between a word and parentheses (with the exception of whatever the parentheses contain) as well as between the period at the end of the sentence and the next word. Ditto for commas, exclamation marks and question marks. Writing whole words in upper case is considered tacky and in poor taste (also yelling in ng's), especially if it's done randomly. "Reiterate" is not spelled with a hyphen (let alone with a space after it). Nationalities and other words describing belonging to a geographical group are always capitalized. A sentence cannot begin with either "or" or "but". Abbreviations for countries are always capitalized (i.e. UK instead of uk). Learn the difference between "its" and "it's", as well between "countries" and "country's". Ditto for "too" and "to".
Also, you seem to be perplexed about certain nationalities, so let me enlighten you: we call Pakistanis and Bangladeshis Asians because they are from Asia.

Simple, isn't it? Likewise, it is perfectly normal to call Swedes Scandinavians and Americans - North Americans. The reason we don't call Britons "Britains" is because it is a word made up by you and no one else uses it.

And finally, language is a live, complex and fluid concept. To reject new words and phrases simply on the basis of their origin is to show an extreme close-mindedness that borders on stupidity. Most repressive governments usually take it upon themselves to regulate the language instead of allowing it to develop naturally. Therefore, your mindset is clearly similar to the one of a linguistic fascist. Notice that even though "mindset" can be described as "how someone thinks", there are few synonims for the word - ergo, there is nothing wrong with the word and the fact that it hasn't been around in the time of Shakespeare does not invalidate it in any way. As long as I'm mentioning Shakespeare, I wonder what you would have called dozens of his made up words which are today standard English. At least you have to agree that it is more natural to say "mindset" than "how someone thinks" in a sentence.

There's another way: a 20 meter hf rig + a ten tec 20/6 converter
OR
a 10 meter all mode + a modified ten tec 20/6 converter - modified
for 10 meters instead of 20. It's a fairly easy mod & works great.
Covers all of 6 - cost me $150. 100 for the ten tec & 50 for the Uniden
President at a hamfest.

Yes, but this picture isn't a good representation of what's happening.
An wire antenna gathers energy from a much larger area than its physical
area. So the wave doesn't have to be incident on the antenna for the
antenna to extract energy from it.

Hi George,
I am sorry but I answered you directely.
I received your email directely to me too....

anyway for all the others readers:

yes!
is a frequency independent structure

keeping constant the cylinders lenght to diameter ratio, the EH antenna
shows the same efficiency from 1 to 30 mhz having the SAME impedance!!!
The only changing parameter is the bandwidth .
these are measurable data.
no bad isn'it? :-)))

no any part of it is resonant
including the network components .
This is measurable data.:-)))

this set apart the EH antenna from any other antenna.

I read some very funny comments ..:-)))
but there is no magic here, no science fiction.
have a peacefull Chrstmas!!!

I have used the HD #14 insulated for several antennas and only one failed in a windstorm by stretching and breaking the copper wire.

The biggest drawback I have found is that the transparent plastic sleeving over the black insulation layer tends to weather quickly and begin to fall off, in the manner of a snake shedding its skin. No particular harm - just looks unsightly until it all falls off.

I too have been paying around $15 +/- for 500 ft rolls at HD.

Guying the tower -
Keep in mind that you COULD, if you needed to, guy the tower at the top, just below where you mount the yagi. With the quad you must have 10 feet or so of unguyed tower below the quad.
Once in my naive days with my first tower, which was a 5 section 88 foot crank-up that was supposed to be guyed, I figured 4 sets of guys on the lower 4 sections would be fine. And I mounted the Gem quad one foot above the top of the tower. Get the picture? First windstorm and the top section buckled about 5%. Took that Gem quad down and been running Yagis for the last 25 years. You put them up, with SS hardware, and shouldn't be doing anything except routine maintenance for the next 25 years.

IF the soft #14
> should stretch a little, so what? Just trim it down and away you go
> again (at least it doesn't SHRINK !!).
==========
Copper is a beautifully ductile metal. When under tension a long length of annealed copper wire does not narrow down at one point and suddenly snap like like brass, steel and aluminium alloys. It stretches out uniformly along its length until the tension is relieved.

There is a manufacturing quality control procedure for electrical grade wire which consists of slowly stretching a standard length between the jaws of a tensile testing machine until it does eventually become brittle, narrow-down at one point and finally break. It is an interesting process to watch. The wire is specified that it must elongate by at least x percent before it breaks. Pure copper has an elongation about 60%.

This occurs because as the wire stretches it work hardens. If one short length should stretch a little more than another then it immediately hardens, becomes slightly less ductile and allows the other short lengths to catch up.

The effect can be felt by attaching 30 or 40 feet of 20 or 22 gauge enamelled copper wire to a post and steadily pulling the other end by hand until it yields and begins to stretch. Under a constant tension it will extend for an inch or so and then suddenly stop as it uniformly hardens a little. To extend it further will require a greater force.

So although an antenna wire may stretch by considerably less than 1% when erected it will not go much further unless the tree is blown down in a storm. Radio-wise a 1% change in length of an HF wire antenna is almost undetectable. In the English climate I have never used anything but enamelled copper (magnet?) wire. Just to make sure, before final erection give the wire a good strong pull by hand which, by guesswork, puts it under as much tension as it is ever likely to receive in the years to come. It also loses all memory that it was ever on a reel.

The most important thing is to prevent kinks developing between coming off the reel and being strung up. Remove all loops in the wire before putting it under any sort of tension.

This of course is written in perfect English (even to the appropriate
usage of "too" - which many native writers here fail to apply
correctly) with nary a sense of understanding. Our correspondent does
not lack proficiency at writing the language, no; but he apparently
thinks the stooge response is endearing and the perfect foil to direct
technical conversation.

>
>anyway for all the others readers:
>
>yes!
>is a frequency independent structure

Ah! Now we lose track of the essential subject (the lack of a noun
before the introductory verb). There is no particular skill in
expressing it in any language, except to do it. However, it does go
to the general impression of the bumpkin.

Why a bumpkin? We have the innocence of the naive to consider, or so
Stefano would like us to treat him. That is why he bubbles and gushes
on so.

>
>keeping constant the cylinders lenght to diameter ratio, the EH antenna
>shows the same efficiency from 1 to 30 mhz having the SAME impedance!!!
>The only changing parameter is the bandwidth .
>these are measurable data.

We are treated with the standard troll offering in perfect English,
and then the bumpkin drawls out:

>no bad isn'it? :-)))

I can just imagine Groucho standing aside, flipping his cigar and
rolling his eyes at this strained mannerism.

>
>no any part of it is resonant
>including the network components .
>This is measurable data.:-)))

Again perfect English (when he wants to) because there is nothing said
of any value (in other words, why cover it up?).

>
>this set apart the EH antenna from any other antenna.

But of course, having said nothing, this offers no distinction at all.
Again nonsense written in perfect English.

>
>I read some very funny comments ..:-)))
>but there is no magic here, no science fiction.
>have a peacefull Chrstmas!!!

Ah, how touching. The bumpkin, hat in hand and stubbing the ground
with his toe, salutes his betters with a yuletide offering.

Surely the experts will cease with their examination so that the
bankers can sign the checks.

Damn! Where's my wallet?! Come back here you *&-!!

>stefano IK5IIR
>

Ah Pulcinella!

You are one of the better clowns. You don't mistake quantity with
quality (even though you DO mistake what constitutes quality).
However the position is filled.

I wonder where your buddy, Francesco (Brighella?), went? He gave us
the set-up and you stepped in for the main act.

Hmm, two guys pulling a Mutt and Jeff routine. Is Francesco Italian
for Phil? ...and there is the IR in your call, Spooky....

Keep em coming

hi
I need the dimensions for the mosley TA33JR yagi. Could someone please
email me the measurement specs..

Thanks john

Hamfests. Look for caps and inductors there. And ALWAYS look
for an ARC-5. That's a WWII military transmitter of various flavors.
A complete one contains a roller inductor and a couple of variable
caps, plus other stuff. There have been some construction articles
on making a good ATU from an ARC -5. I just picked up one at
a junk yard for $20.00 - complete unit, no modifications, no missing
parts. It was my lucky day - I also got a Gonset 101B linear amp
for another $20. The linear was not complete - the HV choke was
loose and rattled around inside the thing when it was transported,
wiping out 2 866 tubes, and 3 811A's. I replaced the 866's with
12 1N5408 silicon diodes - 6 per stack, but the 811A tubes were
about $100 for 4. I also had to rebuild the plate current meter,
which was broken. I glued the meter case back together, and
replaced the movement with one from another meter. Still, even
with the expense and effort, a good find! So the moral is to check
in junk yard, surplus places, hamfests, etc.

Source record: 152225

My 46 ft. random wire antenna is connected to the rx via the RF System MLB
and a RG58 coax cable.
Now I should like to know the impedance of such a system at various
frequencies in the HF spectrum.
I want to test it with the MFJ-259B but I fear that RF energy could damage
or even destroy the balun.
Is the MFJ-259B's radiated energy too strong for this receive-only balun ?
Did anyone try this test ?
Thanks a lot
Pierluigi

The energy from the MFJ antenna analyzer is much too small to damage any balun.

Thanks for this..

I just got my Yule gifts... included in them was an LDG AT-11MP 1.6c autotuner, so this project can now wait a bit. I'll be looking for an ARC-5 or similar unit, and see what else I can get.

Thanks again, and Happy Holidays.

Hi Richard,
thanks so much for this long and accurate analysis of my previous email.
Interesting....:-))
I thought to be on a technical newgroup , and not on a english class....
but in the life we never stop to learn , hence I am thanking you.

Now, I am waiting for some test wrote in italian by you.
I could try to do the same.
BUT here the matter is antennas, new antennas. I have just answered to a
specific question.

I am sorry you concluded my message was ambiguous or having a "double
face".
My statement, I think, is very clear:
" THE EH antenna is a frequency indipendent structure"
keeping constant the cylinder lenght to diameter ratio, the antenna
impedance is constant also.

Please tell me another traditional antenna having the same feature.

You say I have said "nothing". Well ,is your opinion.
I have time, I can wait.
I am sure you will see soon what this antenna can do and HOW it works.

In the mean time this "pulcinella" or Chico Marx wish you all the best for
happy Xmas.
Of course I am saying that .."rolling my eyes" and flipping my cigar...:-))

Hi Stefano,

I think you really mean that the EH antenna is a frequency DEPENDENT structure. This is because for each frequency the antenna must be built with a certain cylinder length to diameter ratio to obtain the desired impedance.

A common dipole has the identical characteristic. The length to wire diameter ratio must be the same for every frequency if the impedance is to be the same.

Richard was a little rough on you but his point is correct in my judgment. In English, the word "independent" used in the way you used it means "without dependence" or "lacking dependence" or "not related" or "unrelated".

You will agree that one EH antenna must be built for each band where a 50 ohm impedance is desired. This would mean that the EH antenna is frequency dependent, just like a common dipole.

Stefano- I'm sure that a part of the problem is definition of words, in English. For instance, if you say "It is frequency independant", that is a "statement", but not neccessarily a "fact". For a statement to be confirmed as fact, it must be subjected to independant scrutiny for verification.
You have made many statements, but we have not seen any of them confirmed as fact, despite your statement that they are facts. Your statement does not make it so.
Additionally, you have said that it is up to the doubters to prove you wrong. - not so- it is up to you to provide proof (not just statement) that it works as you have described. It is YOUR claims that are in doubt, therefore it is YOUR problem to substantiate them, not ours.

If you actually believe this, could I interest you in some oceanfront
property in Little Rock, AR? The water in that area has the spectral
purity needed to give the illusion of standing on the beach in
Galveston, TX. The Arkansas crawdads needed to give the illusion of
crabs biting your feet are optional. :/ MK

Hi Roger,
thanks for answering me.
NO Roger , I mean exactely what I said.
You are wrong.
The cylinder lenght to diameter ratio influnces the BW and the pattern
ONLY.
The antenna impedance is constant , the antenna efficiency is constant
VARYING the F.
That's the EH antenna.

think of it:
a eh antenna built on a 4" support having a cylinder to diameter ratio of
3.14:1 shows 2368 ohm of rad. resistance (resistive)
Well this RR is constant from 2 to 30 mhz...and ,may be, more....

the bandwidth of such antenna with 1.5:1 ratio (the radiant part is about
1' and 4") is about 200 khz at 2:1 of swr and about 400 khz at +- 3 db.
These are measured data.
hence the total Q is low.
How can be explained with such short antenna?
The same sized antenna ,tuned on 14 mhz, shows about 1 mhz of BW.....

a 1' and 3" radiant eh antenna on 14 mhz built on a 2.5" support shows about
1.5MHZ of BW at +-3 db.

the eh antenna can be matched easily with 50 ohm line independently of his
size....and his working F.

The eh antenna can have his radiation resistance dependent by a phase delay
between the applied voltage (coax) and the current on the cylinders.Hence
the RR is phase dependent.When the phase is away from the need one, the RR
goes to infinity.
No one antenna can have this behavior.

sincerly stefano IK5IIR

This says nothing and perpetuates the carefully mocked-up stereotype
you are culturing for this bumpkin act m'boy.

>I thought to be on a technical newgroup , and not on a english class....
>but in the life we never stop to learn , hence I am thanking you.

A careful slip in the English to force the bumpkin approach. Thankful
indeed? You still need to experience Shinola to truly perceive the
quality of your bounty.

It takes nothing of translation to choose to either respond to the
English analysis, or the technical analysis I and others in the past
have offered. You have chosen to focus not on the technical,
obviously; and for good reason, you have nothing to offer except these
home-spun testimonials in the aw-shucks give-it-a-try mold.

In that regard, you are a day late and a Lire short. There are more
folks here who HAVE tried it than you could imagine - including yours
truly. A simple review of the archives reveals your poverty. To this
point, you are merely an intellectual tourist with the wrong film for
your camera.

>
>Now, I am waiting for some test wrote in italian by you.

You answered nothing, you simply made the same repetitive statement
without a grain of evidence contrary to the experience of those who
HAVE built this antenna. In other words, those who have built this
can tell you "act" like you don't have a clue.

>

Ah yes, the standard stooge response written in perfect English once again. It is revealing how the variation from clear Oxford English to itinerant Street Peddler fractured English follows your purpose:

Ah Pulcinella!

You elevate yourself to compare yourself to Groucho Marx. At least most of that nonsense crypto-bumpkin style evaporated with this analytical exposure. You really should abandon it altogether as this negative stereotype of Italians is considered offensive here in the US - especially when it is done for commercial gain.

>Please tell me another traditional antenna having the same feature.
This is called misdirection. It is part of the charade given you declared a financial interest in this design.

In fact, this last point reveals a common attitude we found with one departed and past frequent correspondent. There seems to be a strong correlation between financial interest and clouding the issue for "exotic" designs.

Hi Bill,
thanks I got the message.
I knew that.

For me the "facts" are in the antenna behavior.
I mean I built so many of them....and always I got those facts...
The EH works exactely as a full vertical or dipole , getting the same signal strenght, the same fields strenght
On my garden I built a "perfect" vertical on 7 mhz band.
A 1/4 wav. pole with almost 120 radials (1 miles of wires) on the ground.
Well my 1' and 4" EH performs exactely the same.ON rx is better because shows LESS noise.
For me these are facts.

But I know what you mean...we think to have a "anecoic chamber" test soon....
on that way there will be plenty of evidences.
Sincerly Stefano IK5IIR

HI Mark,
ah ah ah...-)))
Ok I am interested....
but the EH antenna is not resonant , in any part of the spectrum...
is a phase dependent antenna.
stefano

Stefano..

Is, by chance, the EH antenna constructed over the same garden with the 120
radials
(1 "miles" of wire')?

Have you figured out why you can't use a choke balun on the antenna without
"risking
damage to the transmitter"?

> ops and now they hold a fcc license.

AHHhh - "a rose by any other name is STILL a rose"

OR, to break it down into language even a CBer can comprehend - obtaining a Ham License does NOT
automatically, or instantly, transform a raving crude IDIOT into a useful, considerate and law
abiding operator. BUT, CBers entering the Ham ranks soon find that their former operating habits
loom as objectional on the Ham bands as does a fart in church - and they quickly either modify their
habits, or LEAVE...

Ignorance is curable - but rank, dedicated STUPIDITY is FOREVER!

But YOU already know that from long-time personal experience, don't you...

wrote:

>
>
>Hi Richard,
>thanks so much for this long and accurate analysis of my previous email.
>Interesting....:-))
>I thought to be on a technical newgroup , and not on a english class....

Now to remove the gloves....

BEGIN QUOTE FROM SOURCES ABOVE

1. How reliable is the source of the claim?
Pseudoscientists often appear quite reliable, but when examined
closely, the facts and figures they cite are distorted, taken out of
context or occasionally even fabricated.

2. Does this source often make similar claims?
Pseudoscientists have a habit of going well beyond the facts. Watch
out for a pattern of fringe thinking that consistently ignores or
distorts data.

3. Have the claims been verified by another source?
Typically pseudoscientists make statements that are unverified or
verified only by a source within their own belief circle.

4. How does the claim fit with what we know about how the world works?
An extraordinary claim must be placed into a larger context to see how
it fits.

5. Has anyone gone out of the way to disprove the claim, or has only
supportive evidence been sought?
This is the confirmation bias, or the tendency to seek confirmatory
evidence and to reject or ignore disconfirmatory evidence.

6. Does the preponderance of evidence point to the claimant's
conclusion or to a different one?

7. Is the claimant employing the accepted rules of reason and tools of
research, or have these been abandoned in favor of others that lead to

the desired conclusion?

8. Is the claimant providing an explanation for the observed phenomena
or merely denying the existing explanation?
This is a classic debate strategy--criticize your opponent and never
affirm what you believe to avoid criticism. This stratagem is
unacceptable in science.

9. If the claimant proffers a new explanation, does it account for as
many phenomena as the old explanation did?

10. Do the claimant's personal beliefs and biases drive the
conclusions, or vice versa?

END QUOTE

Please note that this is not multiple choice, nor is it best 7 of 10
for a minimal passing score. Any hit invalidates your premise.

Let's score EH to stefano's posted data and references:

1. - HIT, reliability 0;
2. - HIT, calling their design fringe is being hospitable;
3. - HIT, no outside reliable sources have confirmed their claims;
4. - HIT, their design announces to the world how it does not fit;
5. - HIT, they carefully avoid negative data;
6. - HIT, the preponderance of data negates their claims;
7. - HIT, they carefully avoid negative tests;
8. - PASS, only fraudtenna has this arrogance;
9. - PASS, only fraudtenna has this arrogance;
10. - PASS, only fraudtenna has this arrogance.

Hi Peter,
Ok I got what you mean...
The antennas are, of course, detuned during the tests...always

probabily you are right, at the beginning of this story Ted did some
confusion on this topic.
Here in Italy many hams tried to use any sort of line isolation
Choke balun, rf transformer to isolate to DC, and any sort of....but the
antenna performed the same.
The line has not to do with the antenna performance.
thanks , bye Stefano

He didn't ask about detuning.

The first question can be answered with a yes or no, it constitutes a
fact about the antenna system.

>
>probabily you are right, at the beginning of this story Ted did some

Hi Dave:

In case you weren't following, many here were discredited, threatened with civil action, and shamelessly libeled as a consequence of posing such honest challenges. Come to think of it, Scientific American recognized the very person who initiated most of it on here! Perhaps Scientific American's editors ought to pay a little more attention.

centre section 18' 0.5"
All measured to the end of the traps.
Boom director to driven 5', driven to reflector 6' 10"
There were two versions - code 1 for cw and code 2 for phone.
Basically the centre sections are adjusted for best resonance.
Be careful - this antenna can fire backwards if you deviate too far
from the above sizes!

Just jumping to a possible unwarranted conclusion. The person did not
state whether there was insulation between the shields, or not. I assumed
that it did not.

Grounding at one end only does not do anything for electical noise, one
way or the other.

The usual reason for only grounding one end is to eliminate a ground
loop.

> Please tell me another traditional antenna having the same feature.

I have one. It is in a shielded enclosure and is called a dummy load.

In my experimenting, which is admitedly limited, I have found that:
The broader the bandwidth, the less efficient the antenna. Make it
broad banded enough, and almost all the energy gets lost as heat.

If your last sentence is correct, then the one before it cannot be true
as well. If the impedance and efficiency are constant, then the term
"bandwidth" does not apply.

> think of it:
> a eh antenna built on a 4" support having a cylinder to diameter ratio of
> 3.14:1 shows 2368 ohm of rad. resistance (resistive)
> Well this RR is constant from 2 to 30 mhz...and ,may be, more....

Ah, a pi in the sky. The investors must be flocking to you in droves
to provide funding.

> the bandwidth of such antenna with 1.5:1 ratio (the radiant part is about
> 1' and 4") is about 200 khz at 2:1 of swr and about 400 khz at +- 3 db.

SWR is only incidentally related to the antenna impedance. Match the
feeder impedance to the antenna impedance and you will have a 1:1 SWR.
If, as you state, the SWR changes - then the antenna is NOT frequency
independant - nor does it have a constant radiation resistance.

> These are measured data.
> hence the total Q is low.
> How can be explained with such short antenna?
> The same sized antenna ,tuned on 14 mhz, shows about 1 mhz of BW.....

All these examples show that your claims if constant impedance etc
are incorrect.

Bill:

My experience is that someone asking this caliber of questions would only notice that there were two shields when they are separated. Besides, I've encountered plenty of this stuff in buildings prewired for LANs, and it is usually labeled that way ("Triaxial RG 58" or "Triaxial RG 59" depending on the LAN), and has a dielectric between shields. I've got a partial spool of "Triaxial RG-59" which has Teflon dielectric and outer jacket, as best I can determine. Not PE, not PVC, maybe something odd, not Kevlar or the other stuff making old airplanes catch fire -senior moment, name escapes me, ahhh-Kapton it is, so it must be the less common of Teflon FEP or TFE, I have to look it up every time. Anyway, in the coax standard specifications, RG-59, Triaxial, and Teflon are all three mutually exclusive.

I have never worked with LAN cable, so don't know what it is like. I
have worked with multiple shielded cable meant for other services, which
either have two layers of braid or a layer of aluminum foil and a layer
of braid.

I'm not sure if you're suggesting Kapton as being FEP or TFE, but I
believe it's neither in any event. Kapton and Vespel are a couple
names you'll see associated with polyimide, rather a different plastic
than FEP or TFE, but which also has good high temperature
characteristics. Not quite as low loss as FEP or TFE or polyethylene.

Cheers,
Tom

For the first time in decades I cracked my ARRL Antenna Book
and found no reference to such a device. It's c/r '74, printed
'77, so might be just a tad out of date - nothing about fractal
antennae either.

Source record: 152179

Tom:
Sorry, I got to rambling there. I was trying unsuccessfully to list all the wire insulations that I knew it isn't. And I never liked Kapton from the get go. So, I never tried Vespel, which I think is the same polymer by a different manufacturer. And I still haven't pulled the books out, but I believe most Teflon coax is PTFE, so that probably makes this stuff FEP, still one of the Teflon family, but a different chain than TFE.

Source record: 152170

Tom: The 18 HT is a great vertical antenna. Performance on 80 and
40 at medium to long distances is good, but as with all verticals, most
of the time, the close up stations are hard to get due to the normally
low angle of radiation. I have one and love it, but dont use it on 160,
so cant testify to it's performance on that band. A counterpoise is
helpful, especially on rocky ground as I have here in MT, and the
more wire out the better. Best thing to do is put down the radials
and then fill over them, plant some new grass, water the heck out of
it and enjoy the new antenna.

A friend of mine uses 4 of these in a phased arrangement. Works
VERY well.

Good Luck

Tom,
My only experience is listening to them, and the HT-18
is a very nice antenna. It's performance depends on the
ground system you have under it, so put in a very extensive
one! The ground is even more important if you plan on using
it on 160 meters. It won't have the 'best' bandwidth in the
world, but still better than most 160 meter antennas
If you decide you don't like it, send it to me!!
'Doc

>

While I have no personal experience with the legendary Hy-Tower, I know it is the "gold standard" of vertical antennas. What is required to make it work is a good system of ground radials. If you do what AM broadcast engineers do, and lay down a good system of ground radials, you will have very good performance. If you place the HT-18 on rocky non-conductive soil, without an adequate ground-plane you will be sorely disappointed.

If you ever get the chance, examine the antenna of an AM broadcast station. When they build them, they bulldoze away two or so feet of soil, and lay about 120 radials a quarter wavelength long, then ring them with concentric circles and weld them all together, and add ground rods in several places. They they cover it with soil. I'm not saying you have to do all that, or that the Hy-Tower requires a better ground than other 1/4 wave verticals.... only that you are buying a "Cadillac" or "Rolls Royce" antenna. Just as you wouldn't keep your Rolls in a cheap carport or shed that was falling down, you wouldn't want to put your Hy-Tower over an inadequate ground plane.

On 160 meters, you will get a decent ground wave with a vertical antenna. On the higher frequencies, you will get a low angle of radiation. Great for DX, but not so great close in. If you want to chat with folks around within a few hundred miles on 80 or 40, get a dipole and place it fairly close to the ground as an NVIS antenna (Near Vertical Incidence).

As for me, I'm going to buy a AV-640 or Gap antenna that doesn't require the ground system.

Has anyone experience with coax with silver plated shields which has been wet and then dried out? Does the loss return to normal? I've always discarded wet coax, because the loss goes out of sight while wet, but it occurs to me to further ask why does it? The water is concentrated in the shield, which is a cylindrical a conductor, so before corrosion sets in, what is the loss mechanism? The loss in the film of water between the inside of the shield and the outer surface of the coax? Different dielectric constant around the shield wires??? I don't believe the polyethylene or Teflon absorbs enough moisture to count, does it? What am I missing here?

Crazy George,
Probably the layer of water between the dialectric and
the shield, which will certainly change the characteristics
if the coax. How do you get all the moisture out, once it
gets in? Then, how do you correct the changes it ~will~
make in the shield material? Throw it away...

==========
George, does the loss in the cable itself "go out of sight" or is it only at
wet terminating plugs and sockets.

When testing a "wet" length of cable should a few inches be cut off each end
and connections made direct to the wires without any wet connector
materials.

Another experiment would be to strip the plastic sheath off a length of
cable and measure attentuation on it. Then dunk the cable into a trough of
water but keep the cable ends dry. Then measure attenuation again. Would
there be any significant difference ?

Geo,
Speaking from a CATV perspective, cable doesn't get wet like it used to. I haven't seen a piece damaged by moisture in many moons.
On the older stuff though, I think there was a tendency for moisture to take up residence in the foam, at least in the case of many of the foam dielectrics. Given that process takes a long time to occur, "drying it out" is simply not practical. One vendor had a magazine ad showing a length of their cable compared to that of a competitor connected to a suction machine and dipped in a beaker of Kool-Aid to show the benefits of their product. In the case of hardline, there is definitely a bit of suction effect as the temperature swings as well as the normal 'wicking' effect of some dielectrics.
We had a bunch of old cable in a system, both hardline and 59/6/11, all from the same vendor Amphenol, that had the black center conductor disease. For all practical purposes up to 300 Mhz or so there was no noticeable difference in loss. Obviously moisture was at play (and the dielectric did not adhere to the center conductor) and travelled somewhat freely along the wire with little ill effect.
On the other hand, you may recall the old copper braid RG-11 days when the cure for a lossy span was to delash it, whip it like a snake a few times and lash it back up. Methinks that 'cleaned' up the braid which was typically black or green by that time.

So, based on those observations, my guess would be that the moisture that manages to soak into the dielectric is one problem, and deterioration of a braided shield is another. Both may be attributable to a bad jacketing but in the failure mode its a question of which occurs first on any given cable before it is pulled out of service.

From a practical standpoint, if the cable allows moisture to penetrate,
then its no-good anyway except maybe for indoor jumpers.

I hooked up my VX5R to a dual-band amplifier and a mag-mount antenna in my vehicle. Measured 30 watts out of the amp on 446.00 MHz and 60 watts on 144.52. I was able to "work" the same repeaters and friends that I do using Yaesu FT90 and FT5200 mobile rigs so I am pleased with the VX5R + ampl. combination, at least so far (only two days use).

About seven or eight years ago, I was working on a twinaxial cable
with a relatively high speed RS-485 link. The link was failing. To
make a long story short, I discovered that the cable was routed
through a flooded vault. This substantially increased the capacitance
per foot of the cable.

In conversation with engineers at Belden, I discovered that both the
jacket and the center insulators, solid polyethylene, can absorb up to
3% of their weight in water. That's why this cable was not intended
for submersible or direct burial applications.

So if your dielectric *is* polyethylene, know that it does absorb
water and this can have a substantial effect on the dielectric
constant.

I have no idea how you'd go about drying out a cable like that...

Hi all

After 15 months in the new house I think I've got time to put some antennas up!

Only problem is - the layout of the property. I have a good-sized field at the back of the plot - and can easily get 135ft of wire up there for an end-fed long wire.

However - I'd like to keep the RF away from the house / shack as much as possible - as we're out in the sticks and it doesn't take much to upset the TV reception .....

I know you'd normally feed a long-wire simply by bringing it into the shack - but would there be any point in feeding it with 300-ohm twin, the 'spare' core being earthed at the shack ?

How 'fussy' is twin-lead about being in proximity to buildings etc? - due to the way things are arranged the feeder would need to go over the roof of the house on the way to the aerial pole..

I guess another way would be to use an auto-atu at the bottom of the pole that holds up the wire - and then run coax to the shack - but that adds complexity & cost.

Any observations / experiences / bright ideas ?

Thanks
Adrian G0THW

Hi Jake,

As long as you scale ALL dimensions to the new wavelength, ALL
characteristics should follow.

However, if you only scale SOME dimensions to the new wavelength, ALL
bets are off. You should derive some benefit, but if you are going
down in frequency, you shouldn't be surprised that the pay-off becomes
anemic.

HOWEVER

given the posting from Paul, AA1LL:
>"...For a multiwire cage type dipole, the effective cylinder radius (aeff) may
>be determined approximately by:
>
>aeff = a * (n * a0 / a)^(1/n)

>a=radius of cage..."
There is no wavelength criteria insofar as the effective radius except

in relation to the wavelength of excitation itself. So, if I build a cage of 1mm wires with a 10mm cage radius, it will appear to be 20mm thick at any frequency, but as that frequency falls, it will become thinner in relation to the wavelength which is the over riding issue of broadbandedness.

Hi All

I need to put up a HF aerial, trouble is 'very' restricted on space.

Tossing up between a Hustler 4BTV ground mounted vertical with a few redials, and which will be close to small fence and bush's or a Diamond CP-6 which because of the different radial system I could mount 10 feet up on the side of a garage.

Any comments as to which might be the best antenna to use in my situation would be appreciated.

Andy

Source record: 152205

Hi everybody,

Happy holiday season to all. I just ordered some w7fg ladder-line and I noticed that for a few bucks more I could get it assembled with a doublet (Seems like such a fancy shmancy name for a very big dipole?) covering 10-80. I have a 100' x 190' piece of property and some tall (For suburban LI, NY anyway.) trees, so I have the space. I'm shopping around and planning for my early spring project; to erect a 10-80 multiband wire antenna of some sort.

Right now it's a toss-up between this doublet and/or a Carolina Windom 80. Does anybody have any real-world experience with the doublet and or the w7fg ladder line that they can share with me? The "listed" nominal impedance of this "true" ladder-line is 600 ohms. I have a pretty good tuner (Palstar AT-1500C) but I wonder if the Barker & Williamsom 12:1 balun might be better suited than the 4:1 variety.

FYI, here's the links.

http://www.w7fg.com/ant.htm

http://www.bwantennas.com/eng/balun.eng.htm

Thanks for any info you can share with me. It's a learning process. :-)

Hi Jake,

All things being equal, even the twinlead will offer an apparently
thicker radiator than "a regular wire dipole." Of course your mileage
may vary if your regular wire radius is significantly more than the
radii of either in the twinlead - you may then achieve break-even.

Here a comparison can be made using the formula provided:
>given the posting from Paul, AA1LL:
>>"...For a multiwire cage type dipole, the effective cylinder radius (aeff) may
>>be determined approximately by:

>>
>>aeff = a * (n * a0 / a)^(1/n)
>>
>>where
>>a0=radius of each wire
>>n=number of wires
>>a=radius of cage..."

For 2 wires of 1mm radius separated by 20mm, the apparent diameter is around 9mm, or more than double the two wire's combined thickness. This says nothing of efficiency however as the apparent diameter does not come with additional copper surface area to keep losses down.

Taking Roy's model, and exciting it down at 80M could still offer improvement over "a regular wire dipole" if the wire in that dipole is of the same or even twice the radius of his original. Still, modeling is hardly necessary when simple logic, the formula above, and the laws of scaling can be used to judge the difference. It should come as no surprise that to obtain the wideband performance will require similar scaling.

On my wall is a picture of a pre-WWII battleship with cage dipoles hung between the masts. Their cage consists of 6 wires separated by roughly a two foot diameter for an effective diameter of that same two feet (maybe less one inch). This was presuming that each wire was 1 inch radius (rather aggressive, but the picture suggests it as a possibility). If I were to presume a considerable amount of insulation such that the wire was only a quarter inch thick, then the effective diameter would fall to one foot thick (discarding the issue of dielectric added to the mix).

Seems to me, one must make an assumption about the 6:1 balun used to
drop the impedance from 300 ohms to 50 ohms. Assuming a 6:1 balun
that *perfectly* divides the antenna impedance by 6, an 80m folded dipole
is about 14% wider bandwidth (0.4MHz vs 0.35MHz) than a dipole according
to EZNEC. If one assumes that the balun can do nothing except improve
the SWR :-) then that 14% figure might be even higher with SWR=3:1 as
the bandwidth cutoff point(s).

I did sometime ago and found the FD on 80m to be 14% wider than a
dipole on 80m. That's with #14 wires spaced 6 inches apart.

The best way to answer this question would be to download the free EZNEC demo program from http://eznec.com, then do an SWR plot of a dipole with different wire diameters. The equivalent diameter of typical 300 ohm TV twinlead with #20 conductors spaced 0.3" is 0.145".

Depends on the feed wire, since the feed wire will pick up about as much signal as the antenna, if it's approximately the same length as the broomstick. If both the broomstick and the feed wire are vertical, the polarization will be vertical.

From: tek_guy@hotmail.com
Message-ID: <cbf4a67d.0112261223.e14e0cc@posting.google.com>
Source record: 152211

I've got a three element beam antenna for 6 meters (Cushcraft) that I really don't have room for, but I do have room for a two element one. However, if I adjust the elements and spacing, that will throw the feedpoint impedance way off, and I'd have to readjust the gamma match to get 50 ohms.

However, I can't find any references on how to tune a gamma match on a two element beam. I don't have an SWR meter that's accurate at 50 mHz, so I'm stumped at this. Does anyone know the dimensions of a gamma match that will tune a two element beam @ 50 mHz? The dielectric seems to be from RG-8, and the aluminium tubing slides over it.

73s and thanks in advance,

Jim

Hi Bert,

Well, I have been using the classic doublet antenna as my
only antenna for the last year or so. I use 450 ohm ladder
line from the Radio Works company, along with one of their
4:1 current baluns. This combination has worked very well
for me during the time it takes for me to put up a "real"
antenna.

My doublet is up about 15 meters and is mostly flattop in
configuration. I use a tuner of course, and have been able
to work a lot of DX and local stations. My 4:1 balun is in the
basement, out of the weather, and fifty feet of RG-213 comes
up into the shack.

No wire antenna will work as well as beam, but this thing
works amazingly well considering the location and band
conditions. I can heartily recommend the classic doublet
antenna as a good all around performer.

My setup works great for me and might not for you but
here is how it goes.

Transmitter to
antenna tuner to
50 ft coax to
choke ballun to
PL259 female mounted on 9 ft ground rod
The shield gets grounded and the center tap is connected
to my long wire. The wire zigzags through the trees at different
elevations and touches the trees at 3 points. It's a random length
but I think close to your 135 ft. It works so good
I call it my random length, endfed, isotropic, wiggly flinger.

Good luck!

4567. MP-1 Counterpoise question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-26 21:03:28 UTC
From: Tim P <test@test>
Message-ID: <ujek2uca01s9qooh1bkapq6n4b3is083fp@4ax.com>
Source record: 152019

I have an MP-1 SuperAntenna on the balcony coming from an MFJ 949E. I
was wondering if I could hang the counterpoise off of the tuner and
run it in the apartment as opposed to hanging it off the MP-1 outside.

I'm new to all of this so please be kind. 8-)

Thanks,

-tjp

4568. Re: Reason for loss in wet coax?

Source record: 152218

I have encountered wet teflon insulated coax with silver plated shielding, and have found it usable. Two ways to dry it are: To put fairly low power on the line with a dummy load on the far end, increasing power as the power at the load starts to increase: If the jacket is good, hook a small vacuum pump to one end: it will pull the moisture out. It seems possible to restore such line to normal loss. The vacuum should work with other insulation.

Bert,
My personal preference is for the ladder line fed
doublet. With your tuner, it should work just fine
'as is', I wouldn't think you would need an additional
balun, the tuner has one built in. I haven't used a
'Carolina Windom', but from those that I've heard, I'd
stick with the 'doublet'. I'd also 'go' for the longest
length for the doublet that I could 'squeeze' in to
your available space. It won't really be resonant,
but who cares, it'll "work fine, last a long time".

Sounds interesting...
I've no problem with tuning the balanced line at the tx end - have a number of balanced tuners - just read somewhere that the 'cheap' tv ladder-line is more tolerant of local objects than the 'proper' open line - so may play with those ideas

> The wire zigzags through the trees at different

Love it! <g>

My wire can be pretty much in the clear - maybe need a short mast at the shack end to clear a hedge - but mostly it's in the open.

Thanks for the info

It wasn't meant to be scientifically accurate, only to convey
a concept. The radiation leakage out of the car through the
windows would be magnitudes more than the power radiated by
the passive antenna system unless it is tightly coupled in
which case, you might as well have an external antenna.

I'm not sure I understand this thread - a very effective discone for 6M is quickly and easily made from ordinary hardware cloth on very short money, and is a proven efficient radiator, certainly with no kind of 2.5:1 mismatch unless someone has boogered up something. How can one expect any omnidirectional antenna to have "gain" (the way that the term is commonoly used, that is)?

Methinks there is more blowing of smoke & speculative imagination lately around here than factual academic & radiation knowledge...it is like reading the funnies or thoughts of young children...makes it increasingly hard to get insightful, wise or reasonable feedback on a VERY interesting NG subject that involves not folklore, but hands-on trial, research, development and experience, and has much to be learned & to offer.

Cross-posted to: alt.ham-radio.hf,alt.ham-radio.mods,alt.ham-radio.morse,rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.misc,rec.radio.swap

Once-upon-a-time, and it hasn't been all that many years ago, relatively speaking, Amateur Radio sales was a good business. It was a business where there was a place for large and small dealers alike. It was a time when a dealer could load up and go to a swap and basically bring home the empty van and a whole bunch of cash.

Yes, it was hard work and long days, but there was good money to be made.

Somewhere around the late 70s, or very early 80s something changed. The cost of doing business went up. Overhead went up drastically. Now this was around the time of the gas shortage and high prices. People quit buying big ticket items. Rigs were in the process of moving from tube, to hybrid, to fully solid state.

As a group we Hams have always been known to think our rigs to be worth near as much as we paid for them, even a few years later. Hams came to expect to get that kind of payback and were insulted when people wouldn't offer near what they wanted. If someone else had the same kind of rig they'd say it wasn't worth near that much, but couldn't understand why people didn't think theirs was worth more.

Sooo...we pay as little as possible, taking advantage of the hospitality of those dealers who will take the time to work with us and then purchase where ever we can pay the least. <sarcasm on> Then we wonder why there are so few left that offer in store service? <sarcasm off> Amateur radio is not a high volume market and a dealer has to be able to make money at least in one area.

They either have to make money on new rigs, on service, and/or on used gear.

The profit margin on rigs is relatively small, unlike SUVs where the margin has been much larger than on cars.

A dealer can sell small parts at, or close to retail so those help a lot. BUT as one other poster pointed out, a dealer does not have to make a profit on every sale. What they do have to do, is make an overall profit large enough to pay store rent/lease, or in the case where they own it, taxes. They not only have to take a clerks wages out, but there is SS, unemployment, and a myraid of other charges to be accounted. For a low volume business that overhead can be a killer. By-the-way, one of the big expenses is bad checks. You have to sell a lot of rigs to play "catch up" for just one on which the check bounced when you may have been working on a 10% margin.

When all is said and done, they still have to make enough profit to live on from a low voulume, low profit margine, long hours, business.

It boils down to a dealer would have to have a huge turnover in inventory to be able to offer both sales and service to the customer. Even then, every minute away from actual sales cuts into profits which were not large to begin.

Sooo...In general a dealer can offer good mail order prices, or good personal, in store service with higher prices.

IF I know what I want (I usually do, but not always), I quite often use Texas towers, particularly for tower installation parts. (I've always had the parts within two days) I use a local (more or less - He's within about 150 miles) dealer (ComDac) for those items they can supply. I go to AES for those items I need right away that they are more likely to have in stock.

I've found all of the established dealers are good to deal with. They would soon go out of business if they weren't. Sure, each and every one has something go wrong now and then.

The biggest problem today is that there isn't a good place where the new customer/ham can go and personally get good, unbiased advise. The very nature, due to what most of us expect, percludes such a set up.

Hi Bert,
Go with the good old dipole. The W7FB dipole with feed line seems
seems kind of expensive, though. Your lot sounds like it's big enough
for the 10-80 version, but depending on where your trees are you may
have room for the 10-160 version. If you run the dipole wire along the
sides of your lot and turn corners, you can make it fit. Depending on
your tuner, you may be able to work 160m on the 120' version. I have a
200' dipole along the sides of my yard with the feed point at one of
the corners. Works all bands 160m to 10m (just used it to work the
recent 10m contest).

Go with a tuner and don't put a balun at the feed point since the
dipole impedance will not likely be close to 50 ohms anyway. If you
want to transition to coax outside your house, put a W2DU choke balun
at the transition point. I've never had a problem with RF in the
shack.

You may want to ask the vendor if there is any mechanical support for the dipole feed point, or you could buid your own from a small chunk of plexiglass. Drill 2 holes at the top for the rope to hold up the center support. Drill 3 holes at the bottom and use nylon ties to attach the ladder line to the center support. Drill a hole at each side and literally tie a knot with the dipole wire. Solder the dipole wire to the ladder line. The result is mechanically strong and rigid, and the solder joint is not supporting the weight of the ladder line.

You may want to ask the vendor if the dipole wire is insulated (to slow down corrosion). You also may want to cover any exposed wires with exterior caulk.

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-26 23:10:09 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <a0dlcgmbt1@paris.btinternet.com>
Source record: 152033

An 80m band dipole, length = 131 feet.

Resonant frequency = 3.68 MHz.

Bandwidth between SWR = 2:1 points
for increasing wire diameter is as follows -

Wire Diameter Inches	Wire Diameter mm	Band Width MHz
0.02	0.5	0.16
0.04	1	0.17
0.08	2	0.18
0.16	4	0.19
0.32	8	0.21
0.63	16	0.22
1.26	32	0.24
2.5	64	0.26
5.0	128	0.29
10	256	0.32
20	512	0.35

Doubling conductor diameter increases bandwidth by about 9 percent.

Increasing conductor (or equivalent cage) diameter by 512 times, doubles the
bandwidth.

Use program WIRECAGE.

The Gap has no traps and my Titan is a decent enough vertical - pretty lousy on 80 but fair on 40 and better above. It can take the heat. I have run a full KW into it. Construction takes a while but it is not unreasonable. Be sure to guy it if you have any wind as the thing is top heavy. It is not as good as my ladder line fed 102 foot doublet unless the station just happens to be in one of the doublets nulls.

4588. Ladder Line & Inverted Vee

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-27 00:25:11 UTC
From: Ace_On_Par3 <pwhelton@hal-pcNOSPAM.org>
Message-ID: <a0dppn$2c7f$1@news.hal-pc.org>
Source record: 152040

What is the more common way of routing ladder line (or open wire feeder) to an inverted vee? Can standoffs be used to run the line down the pole at a reasonable distance (say 4 inches or so) away from the pole or is it better to leave the center insulator and angle the feeder away from the supporting pole down to the shack?

If standoffs are the answer do you know a good source?

Thanks,
Pat - KZ5J

hy-gain 18AVTWB works quite well on lo bands with radials. on 80, you
really should use more than 2 or 3 radials, if you hv the real estate.
on 40, same story. Other antennas may be better for 15 and up.

how much power are you using to "blow out traps?"

hy-gain 18AVTWB works quite well on lo bands with radials. on 80, you
really should use more than 2 or 3 radials, if you hv the real estate.
on 40, same story. Other antennas may be better for 15 and up.

how much power are you using to "blow out traps?"

4592. Re: Do "folded" folded dipoles work?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-27 01:08:16 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <a0dsa0$8sl$1@knossos.btinternet.com>
Source record: 152044

An 80m dipole using 14 AWG wire has a bandwidth between the SWR = 1.5 : 1 points of 103 kilohertz.

A folded dipole made from common-or-garden 300-ohm TV twin-lead has a bandwidth between the SWR = 1.5 : 1 points of 119 kHz - an increase of 16 percent.

Is it worth it just for the sake of such a small increase in bandwidth ?

The advantage of the folded dipole is that it allows the dipole and feedline all to be made with the same type of 300-ohm line. But a heftier 450-ohm ladder line would have slightly lower loss despite the higher SWR.

Use program WIRECAGE for 1 or more cage wires and for SWR = 2 : 1 at the band edges. It will be seen there's no point using more than 12 or 16 wires in a cylindrical cage. Just sweep through the number of wires until the bandwidth stops increasing.

I had the same idea a while ago while working in a stainless steel clad kitchen. We had mobile phones (900mhz or so) and this room (about 10ft x 10ft) was acting as a very effective faraday cage. I imagined a tiny dipole in the room with a short feed to the outside world to an antenna. Never got round to trying it, but I'm suprised that it's been thought of already. I always wondered if it would have worked. I got as far as cutting a 1/4 wave dipole for it out of coathanger wire. I never used it for the kitchen idea but in experiments with a scanner set to 920mhz it worked very well for RX only. Each element was approx. 80mm, making a very tiny but very effective simple antenna.

I boobed in my previous posting about the 80m dipole. I entered the wrong wire spacing in the program.

The 300-ohm twin-lead folded dipole has a bandwidth only 7 percent greater than the 14 AWG wire dipole.

So my remarks are still applicable.

Support the ladder line 3 or more times the wire spacing from other materials for most or all of its length. Occasional nearly touching over a length of a few inches won't do any harm.

But if you angle the line away from the pole or mast you will need fewer stand-off insulators.

If you would like to bring the ladder line right into the shack, bring the pair of wires closer together for a few inches and pass them through a single insulated hole in a window frame or thin wall.

The general rule of thumb is to space the line from conductive
surfaces at distance greater than 2ï¿½ -3 times the distance between the
line's conductors. In other words, for the so called 450-Ohm line
which has 0.8" conductor spacing you should keep it at least 2" away
form conducive surfaces.

Hey there,

I think it is important.

UHF has a much larger bandwidth signal. CB has a shorter
bandwidth.

SWR in UHF is important. if you can get your hands on a
VHF/UHF SWR meter .. I would recommend it.

Good luck!

It is not clear just what you are trying to accomplish here. Unless you provide more information, no one can help you. If you are only using the antenna for receiving (scanner), the SWR doesn't matter at all. Otherwise, it does, because you can easily blow up your finals if the antenna is not matched. This is equally important on CB, UHF or any other frequency, but it is not a function of the signal bandwidth.

Well, a vertical colinear is an omni with significant gain, but it's rather
narrowbanded.
I think the main misunderstanding is in not appreciating TANSTAAFL as
applied to antenna physics.
I'm perfectly OK with discones, but I understand their limitations, and use
them where their strengths are a real advantage.

Pat,
It really doesn't matter a whole lot. If you want to
use stand-offs, thats fine, if you would rather just let
the line angle away from the support, that's fine too.
The others gave good advice about the 'stand-off' distance,
etc, so no point in re-hashing that...
'Doc

PS - Is this the same 'Pat' that had a 1/4 wave vert. on
80 meters at one time??

If you are using the aerial for receive only then the SWR is not
so important. If it is for transmit too then yes SWR is important
and worth checking to avoid damage to your transmitter's PA.

Note that if you don't have a transmitter for the frequency you're
looking at then an SWR meter won't be any use. The meter needs to see
some RF in order to give you a reading.

Cheers,

Mark.

Grid to filament shorts seem to be the newest common wave of failures
in 3-500Z's.

The filament normally has to be lit to check for a short, and you
normally have to apply several hundred volts of reverse (grid negative
with respect to filament) voltage from a current limited source and
tap the tube gently watching for a short.

At times you can high-pot a cold tube and tell the filament is
misaligned, you get around 5 or so kV voltage breakdown on a good tube
and 2kV or less on a bad tube, but this test is much less reliable
than a hot tube test.

Open or unsoldered filament pins (that can NOT happen with a 3CX3000
series tube because it is not soldered, it probably has a bad internal
weld) is an indication of a high resistance connection in the socket
heating the pin or inadequate cooling.

Many people run the old amplifiers that were designed for 600 watts CW
output and 1200 watts PEP output on SSB (like Drake L4's and Heath
SB220's) at over a kilowatt output on CW, and wonder why the tube pins
unsolder or the sockets contacts give out!

>[As a side note, I have often wondered why circular polarization is >not used for amateur repeaters, except perhaps for antenna complexity. > There is a distinct advantage for reducing flutter, and there are a >number of ways of making omnidirectional circular polarized antennas.]

Hi Jim,

Circular polarization is not used on skywave paths because it INCREASES fading. A tilted polarization like Roy described is not any better than any other polarization.either.

The problem is multipath and other effects constantly are changing " the received signal with signals often arriving a multiple angles taht are all "polarized" differently. With more than one polarization (NOT polarity, polarity is the wrong word) arriving, and with phase being random, you are just as likely to have a null no matter what you do.

It is even worse on transmitting, because circular polarization increases chances there will be phase cancellation on a sky-wave path.

That's why all HF diversity installations use separate receivers that "vote" based on signal-to-noise or absolute signal level, with the best signal capturing the system. I suppose it would be possible to do a DSP system that sorted strong signals from noise, and corrected the phase errors.

To use diversity on 160 meters, I run stereo audio from phase locked receivers and let my "brain" process the signal from the widely separated antennas. There is no possible way to combine the antennas at RF or even at audio without constantly correcting level and phase. If I do attempt to combine them, it simply makes fading and S/N worse a few seconds after bringing the antennas (or receiver audio outputs) into phase!

Transmitting is even worse, because you can't hear the bad effects!

The best transmitting antenna, when multipath is involved, is one that will focus all of the energy with a plane wave (no phase rotation) into the center of the most reliable path. BC stations favor .5WL or shorter verticals over 5/8th wl antennas, because the extra lobes from the 5/8th actually increase fading. The name often used for shorter than 5/8th wave verticals is "non-fading verticals".

Either manually switch the antennas, or use a single polarization.
Tilting the antenna certainly won't help when averaged over time, and
using circular polarization actually can hurt.

No. It is a balanced antenna.

>International Antenna Corp www.iacantennas.com who makes them commercially
>claims that no balun or choke is required...

They claim a lot of things that aren't true. A Bazooka is no different
in any electrical respect than a conventional dipole, except it is
slightly lossier. The extra loss and thicker antenna helps bandwidth.
It does nothing to eliminate the need for a balun.

Source record: 152065

Hi Doc,

Actually my intent was to quickly and inexpensively get on the air. My long term plan was to improve the antenna system as time went on (I was living in Buffalo, NY) and it was in the winter when I put the antennas up. The folded dipole also provided the benefit of requiring less space to hang, which made it easy to string them from my chimney to a convienient tree. I never had the opportunity to make the improvements as I ended up getting transferred to Dallas the following year.

The big thing for me was the folded dipoles got me on the air, and for my operating style, mostly CW rag chew or AMTOR with no desire to collect wall paper, they served me very well.

I did (and still do) miss my 3 element beam on a 50 ft tower, but occasionally some trades have to be made.

BTW, I'm in the process of setting up my station at home again, and I'm starting small with a G5RV up about 25 ft at the center and configured as an inverted Vee. Once I get the station up and running, I'll probably get busy improving the antennas, but after a 7 year hiatus from HF, just getting on the air is a big step. I purposefully bought a house in an area that doesn't have any restrictions on antennas, and I have a small corral with no horse, so there is room for improvement. I'm also now active on moble HF as I put an Icom 706 MK2G in my truck last week.

Source record: 152066

Actually, I never intended to imply that folded dipoles had "superior bandwidth", I did notice that I could move around the band pretty well with little or no need to re-tune things. As with everything, in the world of antennas, you don't get anything for free. I traded efficiency for ease of installation and cost. I was not in a position to run efficiency experiments and research was not my intention.

My objective was to get on the air quickly and cheaply with antennas that would work reasonably well, fit in the space that I had with no major effort, and allow me to operate with my normal style. The plan was to improve as time went on, but of course the "plan" quickly became overrun by events when I got transferred to Dallas, and now I'm in Tucson. Try moving a tower and beam around the country!

Greetings, I'm looking for information about potential indoor antenna solutions that would work well in an attic (homeowner's association prohibits external antennas as well as my appropriations committee (a.k.a wife). Our attic is 8+ feet high at the ridge. The J pole looks like it would work quite well?? Your pointers, references, links and help is most appreciated. 2, 6, 10m and 70cm.

Thanks,
-Rob

4615. Re: What is a good 5 band vertical? Gap??

Check out the Butternut HV9 too. I used to have a Gap Challenger and had good luck with it. It didn't hold up in the wind to well. I had to buy the middle pipe because it bent, but then probably any of the others on the market would have bent too. The wind was only about 25 to 30 mph when it bent. One thing I like about the Butternut is that you are able to work 17 meters and with the Challenger you can't.

Yo, Tom...

By CW, are you talking keydown as in RTTY work, or the normal duty cycle
for
Morse CW? What is the difference in average dissipation for the SB220 when
running CW or SSB? I always thought the CW power level was to comply with
early FCC rules which limited a transmitter to 1000 watts DC input power.
I've run my SB220 in the SSB position for 1200 watt output on CW contacts,
but only for casual dxing--not heavy duty contest style operations.
I am kind of surprised that a dual 3-500 design would be limited to 600
watts
on CW, seems to be a waste.

The SWR always matters.
Signals bounce off impedance transitions.
Transmit signal bounces off, and so does receive signal.

A CB Swr meter won't work at UHF though, because it's sampling line section
is a large fraction of a wavelength long. RS sells a good little meter,
it's no Bird, but at $50, it's the price of the carrying case for the bird.

A vertical omnidirectional gets it gain like any other antenna.
In this case, the radiation pattern is flattened, like a pancake,
with the maximum gain (hopefully) at the horizon.

Don't be too hasty in dismissing the 'CB'-centric SWR meters.
The good ones (however you define a Good One...) work at 50 mcs just fine.
I've got one that works well on 144 mcs.

One trick is to mount the SWR meter _right at_ the antenna. Don't
mount it on the back of a rig and attempt to fiddle with the antenna
some 100 feet or so down a piece of coax.

On 144 mcs I use an HT bolted directly to the SWR meter -- which,
in turn, is bolted directly to the antenna. The whole thing is
mounted off of a _wooden_ stepladder pointed straight up with the
reflector as high off the ground as possible. (IIRC, I tuned
my 3-el 6M CC by mounting it out off the peak of the roof of the
garage.)

YMMV

As to futzing with the gamma match. Time, patience, and simple,
dumb luck are your friends.

If you have an indoor antenna range and a network analyser, things
are different.

Hi, folks:

I've reviewed the threads "Whole House Surge Suppressor" in comp.home.automation, and also "single point grounding" on rec.radio.amateur.antenna. Good information, indeed.

I am still perplexed and would like advice on grounding my home dish setup. I have a roof-mounted dish with a cable grounding block mounted at the cable entrance. I also have the cable grounded to a cold water pipe in the furnace room, which is a cabling hub or distribution center for coax, CAT-5 (for phone and LAN), and alarm wire I have run.

To make things a little more complex, I am runing coax between equipment in the basement and equipment upstairs. This coax is currently grounded to the cold water line at the cabling hub.

Ideally, from what I have read, everything should be grounded via a "star ground" to the power ground at the meter. This won't work in my case for two reasons: the meter is at the opposite end of the house from the cable entrance, and the water line is most likely not connected to power ground. It would also be very difficult to run a 50' ground wire from cable entrance to power ground or to anywhere else. So I think I have the following options:

a) Leave it as-is with multiple grounding points. I have read that such a configuration can actually cause trouble.

b) Unground cable at the cable entrance, leaving it grounded to the water line. This would leave a 50' interior cable run (next to copper A/C pipe) before it is grounded.

c) Unground cable from the water line at the wiring hub. Then I could either leave intact the ground of my in-house (non-dish) cable running between equipment or disconnect it and let it float.

I'd appreciate any thoughts, suggestions, references and guidance.

Thanks,

Fred Elbel

When I was in a similar situation I drilled a 3/8" hole in the roof directly over the attic access hatch, which was in the master BR closet. This allowed me to raise a vertical dipole so that the upper half was outside at night but lower it so only an invisible couple inches protruded during the day when snoops were about. Just to be safe, I told the neighborhood gossips that I was going to rent my place to the county welfare office to sublet to welfare families if I couldn't pursue my hobbies. When my wife complained I swapped her for a lady who shares my interests. Life's too short to put up with any BS.

The statements by Allod---- are quite true. There was an article
(QST-CQ-?) several years ago about steps to take to improve the common
CB SWR meter for use at higher freqs- I took the cover off an old
Siltronix CB unit, and found it was better made than the unit in the
article, and better balanced. I matched it against some VHF units some
friends had, at 2 meters, and found it to be very good.
In addition, "accuracy" is not needed for most applications- what you
are usually needing is to find a minimum, not a specific value.

The SB220 and other amps were designed to operate at the legal power
at that time, which was one kilowatts plate input. The manuals
describe correct operation, but most people ignore the manuals and
hammer the amps.

>What is the difference in average dissipation for the SB220 when
>running CW or SSB?

There is a lot of difference, and it varies over a wide range with
duty cycle. It may seem like a waste to operate 3-500's at 600watts
output, but that's what the amps were planned around. No one had any
idea the power output limit (based on about 60% efficiency) would be
almost tripled on CW and RTTY. If you look at the power transformers,
they are smaller than transformers in many single 3-500Z amps today.
They also have less airflow.

That's part of the reason pins overheat and the solder melts.

First question:
Are there any currently available commercial tuners that provide truly balanced output, ie. not coaxial output to a balun but rather matched output L or Pi circuits -- perhaps fed with a balun.

Second question:
I currently use a J.W. Miller Model 2500 automatic tuner with coaxial output feeding about 10' of RG213 to a 4:1 current balun which feeds 450 ohm ladder line to my non-resonant dipole. In the opinions of the gurus, would a truely balanced tuner, as described above, provide much of an inprovement?

73 and happy new year to all, Mont - K0YCN

Mont,
I'm not sure exactly what you mean by 'balanced' output
tuner. I think you might be refering to a 'link' coupled
tuner like the old Johnson MatchBoxs. If so, then I don't
think there are any being made commercially. There are a
number of 'balanced' output tuners, but they usually have
a balun built in to get the balanced output.
Did I get close?

I have 3 inverted V antennas cut for 10, 15, and 17 meters in the attic with feed
points near the apex of the roof. Some trial and error required to get the right lengths,
but have had good results using separate
coax lines to each antenna. A matching
network at the transmitter end also allows
me to achieve a good match on 20M with
the 17M antenna.

>Are there any currently available commercial tuners that provide truly
>balanced output, ie. not coaxia

Don't think there are anymore.
>would a
>truely balanced tuner, as described above, provide much of an inprovement?

A balanced antenna fed with a true transmission line should not care about tuner type. But, If the transmission line is in the induction field of the antenna it could upset the balance a bit. I use a T type tuner with choke "W2DU" balun where my coax transistions to 450 ohm line. I don't have rfi or tvi, but did before I added the chokes, (two of em').
You will not get an improvement by adding balanced tuners, chokes ect. unless you have problems with rfi or, the pattern from your antenna is not what you expect. Mostly, I add stuff to my antenna system to try to increase the microvolts at the other end. Balance (tuner or otherwise) will help the other end only if it effects the antenna pattern. A complex subject, has been discussed before, search archives.

Alas,

We always want the maximum performance from a minimalist antenna. Sorry to say, the thru-glass antennas don't work very well. IF you get a chance to compare one of these to a 1/2 wave or 5/8 wave VHF antenna, you will notice a huge difference just in the receive alone. If you live close to lots of repeaters, it might be OK. IF you are out in the boonies and repeaters are scarce, you might want to reconsider. It is a fairly simple matter to fashion an "L" bracket and mount this in the channel between the fender and hood with small screws. No-one is going to see these holes, and they can be repaired with JB Weld when you trade. If you keep cars as long as I do, it won't matter anyway. If you have a luggage rack on top of your Cherokee, you might consider a mirror bracket attached to one of the rack's bars with longer stainless bolts. Then you can run the feedline in the door channel and find a place where the coax won't be pinched. If you want "pretty", the little thru glass antenna is the trip. If you want PERFORMANCE, go with a Larsen, Diamond, or Comet dual band. This top mount, BTW, is the very best place for your VHF/UHF antenna.

Hope this helps.

The on-glass antennas like those made by Larsen do work,
but they are a compromise. I have a few of the monoband
antennas (2m and 440), and I would guess that they are at
least 3 dB down from a real antenna. I would imagine that
a "dual band" on glass antenna would be a severe
compromise, and a friend's experience bears this out.
And many trendy, newer vehicles come with dark
gangland tint which further attenuates the signal.

> I am looking to mount a dual band radio in my Cherokee
> and don't want to drill holes in the body.

You only have to make one 3/4" hole per antenna.
The roof of your beast is an excellent ground plane.
You didn't mention its age, that would be helpful.
Anyway, get a 3/4" hole saw and be done with it.
If you are nervous, buy some touch up paint for the hole.

The dealer I bought my radio from recommended and
> Antrron # GT-2440H. Any feedback on this antenna
> would be appreciated.

I've never seen an Antron antenna for VHF or UHF,
perhaps they are new to this arena. Why not go with
an NMO antenna from one of the reputable vendors
(e.g. Comet, Diamond, Larsen, Maldol, etc.)?

You will get lots of negative feedback on glass-mount antennas. Most coming from those who either have not used one, or installed one incorrectly. I have used a Larsen dual-band glass-mount on my '93 Jeep Grand Cherokee for nine years with very satisfactory performance. Our repeaters are out up to 100 miles in mountainous terrain. If I want the last ounce of performance, I put a 5/8-wave Larsen in the middle of the roof, but then I can't get in the garage. I have used the 5/8-wave maybe 3 times in 9 years. I have never felt "antenna challenged" with the glass-mount. If you try something other than a Larsen then you are on your own.

4648. Water in coax

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-28 04:10:08 UTC
From: ricknj10@hotmail.com
Message-ID: <3c2bedbe.311333371@news.eclipse.net>
Source record: 152151

Today I noticed my 2 year old 40 meter inverted vee had 3:1 SWR and
the IC-746 was cutting back power to 20 watts on 7.1 MHz.
I tested the antenna with the MFJ 259 analyzer and didn't get a good
dip like usual.
The feedline drops down the tower and is spliced into the coax that
goes to the shack with PL259s and a barrel connector that is taped
very, very, very well - tight, many layers, etc. No way could water
ever get in that connector. Well when I opened it up to attach the
MFJ there, I could shake a little water out of the connector, several
drops.
So the question is - how did the water get in there? Wicked down 80
ft from above, through a coil of excess length? Doesn't seem possible
to me......
I took the whole mess into the shop and rewired the connections at the
feedpoint. When I trimmed back the coax there it was dry and still
had shiny copper braid (RG8X).
Just wondering if I need to protect the feedpoint from getting rained
on? Maybe I will build a little cover for it out of a plastic cup
that I could suspend from the rope holding the antenna up.
Any comments?
One more thing. I measured the attenuation of the cable in the shack
and it was 1.1 dB at 7 MHz, 85 ft of RG8X.

From: ricknj10@hotmail.com
Message-ID: <3c2bf565.313292179@news.eclipse.net>
Source record: 152153

Purely by coincidence I just posted a question relating to my
experiences with wet coax (then downloaded new postings and saw this
thread going on).
See my posting titled "water in coax" that was posted Thurs evening.

To summarize here - I DID measure the coax that was an 85 ft feedline
to my inverted vee on 40 meters. The PL259 at the base near ground
was wet, but the top (feedpoint) end appeared dry and the shield was
still shiny. I clipped it off there, and before soldering it back to
the antenna wires I measured it at 1.1 dB loss (85 ft of RG8X at 7
MHz).

That question remains unanswered. I'm 25+ years in the cable business
and any vertical inline splice seems to collect water over time no
matter what you do (other than make it quit raining). Bend it around
horizontally and it will go forever.

One idea might be to make notches at 3-4 places around the circumference
with a hacksaw....or at 4tpi you could use a piece of cord in between
turns while pulling it taut to get a nice, pretty spacing.

hey bob
once you put an antenna in the attic and tear up the TV and the telephones
your wife will beg and plead with you to put something outside
there are a good many stealth antennas that can be put outside but still be
out of site below will be a website with plenty of ideals but i have a couple
as well
check your deed restrictions and see if your allowed a flag pole if so you can
build a PVC flag pole and hide an HF multiband vertical in it
or take some antenna wire and 1 inch stand offs and go all the way around the
roof line of the house and then run both ends into the hamshack to the tuner
if the housing people ask tell them its a messanger line to hang xmas lights
from
as for VHF thjere is the ventenna which is a dualband Jpole hiding in a chunk
of PVC pipe that slides over the waste stack on the roof and just looks like a
overly long waste pipe
or i seen a weathervane that was a 2 meter vertical that you would put on the
roof and no one but you would know
here is that website
http://www.ac6v.com/antprojects.htm

and if all else fails pack up and move sell the house and buy one that isnt
deed restricted.....grin
happy hamming

Max,
I guess it depends on how much trouble you want
to go to. The 'no expenses spared' route would be
to take the coil form to a machine shop and have them
cut a groove at 4 tpi. The cheap way would be to just
wind the wire on the form an 'bolt' it down tight, by
using an appropriately sized 'spacer' (tape, cord,(?)).
When you have the windings how you want them, fasten
the ends to the form and remove the 'spacer'.
(It's more expensive, but the 'grooved' coil is
the 'best' way to do it.)
'Doc

PS - Did you ever get your mobile antenna to work?

Actually, in some circumstances, a thru-glass design works better than traditional designs. This is because the higher dielectric constant of the glass, plus a lower dielectric loss tangent (compared to normal carbon filaments) yields a focused EM field with lower group delay and a higher transmissibility factor (tau). So, the Effective Radiated Power (ERP) is higher (albeit in a narrower beam). Try it - you may be surprised!

If you are going to go to a machine shop, why not just have them wind the
coil?

Close wind it with more turns than you need and stretch it. The ends tend to
get distorted but that is what the extra turns are for. Cut to length.

4664. 2m Horizontal Loop Antenna Plans

Newsgroup: rec.radio.amateur.antenna

Hi,

I've heard that these small 2m horizontal loop antennas (sometimes stacked 2 or 4 at a time) (also known as sqkloops?) are excellent for sideband. I see them offered for relatively cheap by KB6KQ(.com). However, my Dad and I are interested in building one for fun. Does anyone know if the plans for this type of antenna can be found in QST or in the Antenna book?

We are interested in using one or two of them for 2m SSB (we're just getting started).

Thanks for any help you can provide,

Jason

Here in UK we call them Halo's, basically a dipole bent into a circle,
or "squalo's' bent into a square, and fed with a gamma match.
I have seen some where the dipole is centre-fed and capacitivly tuned
between/across the ends.
Not too bad for horizontal mobile aerial, but down on a dipole.
Cardiac radiation pattern with null at the ends.

I have dimentions somewhere, but nothing too critical for you to fail
with 'cut and try' tuning. Shout if you want specifics and drawings.

My experience from running lots and lots of LDF4-50 for a 928/952 MHz telemetry system for my employer is this:

Electrical tape alone will not seal a connector up for long, horizontal, vertical, whatever. Now, mind you, our connectors and line are slightly larger than what you're using. We tape everything up using and entire roll of electrical tape, then paint scotchkote all over it, and then layer two more such combinations of the two over this gooey mess.

Our connectors sit at the tops of towers and telephone poles exposed to rain, sun, wind, heat, and cold. The half life of connections set up this way is about ten to twelve years. Tape alone won't last a year.

I've heard good things about some cable sealants of various sorts, but since so much of our work is done by electrical contractors, we settled on something we had solid experience with and was easy to stock.

Bottom line: electrical tape alone will not seal a connector, no matter how tightly you wind it.

Rick, K2XT wrote:
"Well when I opened it (the coax connector) up to attach the MFJ there,
I could shake a little water out of the connector."

Could be a leaky coax jacket or a leaky wrap on a connector.

It is unlikely that several drops of condensate came from air confined
to one connector.

My experience is that good waterproofing is obtained by tightly
wrapping a jacket hole or coax connection with electrician`s rubber
tape, sticky surface toward the coax, then covering that wrap with
friction and/or vinyl tape or sleeve, and finally, doping the whole
mess. Done right, that spot is air and water tight almost in perpetuity.

Yes. There are two manufacturers. Palstar -- They use a balun at the
input of the tuner and an insulated L network. It is an expensive tuner!
See http://www.palstarinc.com/palmain.htm

The other is the BLISS Z Match. See
http://airwaterkinginc.purification.com/BlissZMatchMaster.htm
They use a balun at the input and two LARGE variable inductors to form a
balanced L network.
They have a low power version, a high power version, and a motorized
high power version.

I do not have either of these tuners. See also the new ARRL Antenna
Handbook if you
wish to build one. This one is similar to the Palstar as I understand
it. Or http://www.cebik.com/link.html, like the Johnson tuner or
http://www.vcnet.com/measures/bbat.html,
the basis for the BLISS.

If you buy one, let us know how you like it!

hi jason
i dont know what your situation is but 2 meter SSB is not like FM it takes a lot more than a simple unity gain antenna to be able to work SSB and it takes very good feedline and height the higher the better if you where going to be using the halo for mobile i would say go for it but for a base station do yourself a favor and get a good high gain yagi atleast 13 elements on a 15 foot boom feed it with a low loss coax say 9913F or LMR400 and get the antenna as high as possible around 50 feet would be good i have worked a good number of states here from florida with that height and 2 cushcraft 11 ele yagis
good luck

Doc wrote:
"Probably the layer of water between the dielectric and the shield,
which will certainly change the characteristics of the coax."

Sure, if the braid corrodes and the water goes away. Impure water in the braid may actually reduce coax loss. When this water shunts connector insulation, watch out! Unfortunately, water usually migrates to a connector where it becomes a short-circuit, more or less. One form of migration is evaporation and condensation.

Moving the balun to the input of an L network does nothing to improve
balance, or make the balun work better. The core sees exactly the same
magnetization forces, and balun choking requirements so far as voltage
are exactly the same.

The only thing moving the balun does is reduce differential mode
stress between the balun wires, which is normally not an issue at all.

It certainly does!

Having a balanced system means the entire system, even the transmitter end, must be balanced for voltages and currents.That means each wire, with respect to "earth", must have equal and opposite voltages and currents.

Many times you can get away with less than perfect systems, but les-tha-perfect balance at BOTH ends of the feedline can equally cause problems.

Hi Mont,

4:1 baluns are generally poor baluns to use in systems like yous. That
is because as a general rule voltage baluns, which your 4:1 balun
certainly is, have the poorest ability to handle mismatches outside of
their design impedance.

The input impedance of ladder line feeding a dipole varies greatly
with frequency. It is unlikely, unless you planned the system
carefully and swicth feedline lengths with band, that the balun sees
anything near its design impedance.

Choke-baluns are much more immune to these problems, and are the balun
of "choice" in multiband systems. It often is a good idea to use a
minimum of 50-ohm feedline at the antenna side of the tuner also.

>> > Is the bandwidth as advertised and are they easy to assemble?

Rule number one, don't expect any antenna to work like a manufacturer claims.

If you run high power, you also might have problems with the Gap. The coaxial stubs used in some are very lossy, and do not handle power well.

Read the ARRL Antenna reviews on the Gap antennas, and you might invest in a copy of "HF Vertical Performance Test Methods and Results" by Ward Silver and Steve Morris.

The ARRL compared a Gap something to a low dipole and a conventional OLD trap vertical. You would probably be suprised at the on-the-air test results after reading advertisements.

Ward and Steve actually installed verticals and measured them on a test range, so they have direct actual results of how various verticals work. The book is a great investment BEFORE spending hundreds of dollars on antennas. You can get a copy at Champion Radio Products or by e-mailing upthetower@aol.com

Long term loss in coax that has been wet comes mainly because the
braid tarnishes, and skin effect forces current to flow either through
hundereds of poor connections where the weaves lay together or else
forces it in a high impedance path weaving in and out.

That is why once the braid tarnishes, the cable is toast even if dry.

Tom, W9JI wrote:
"Circular polarization is not used on skywave paths because it INCREASES fading."

Increased fading may be debatable. But, skywave means reflected by the ionosphere. On reflection, the rotation sense of a circularly polarized wave is reversed. Cross-polarization loss may be 30 db. See the ARRL Antenna Book section on helical antennas for details.

Helical antennas have been used for TV to suppress ghosts because the receiving antenna is sensed to capture the direct wave while the reflected wave suffers the cross-polarization loss.

The ionosphere is subject to many changes in reflection properties, some of which are rapid. Thus, a polarization sensitive antenna can be hurt as well as helped by instantaneous conditions.

Perhaps a dual-diversity receiving system could work well with one antenna sensitive to right-hand rotation in a circularly-polarized wave while the other antenna is sensitive to left-hand rotation. Separate receivers must be used and the better receiver at the moment is selected for monitoring.

Two or more common antennas spaced 10 wavelengths or so apart in a typical space-diversity system are probably a better solution to the fading problem at h-f. That`s probably why they so common. But, polarization-diversity is used at microwave frequencies. Some of the dishes hung on those towers have dual feeds which are cross-polarized.

Best regards, Richaed Harrison, KB5WZI

I wrote:
"Done right, that spot is air and water tight almost in perpetuity."

I meant perhaps more than the 10 or 12 years mentioned by another respondent. Nothing is permanent.

I`ve found it worthwhile in some cases to always wrap inclined or vertical cables with tape as one might install shingles. That is, start at the lowest level and work up. Put the first tape wrap turn at the bottom and overlap it slightly with the next turn. This uses gravity to shed water.

Best regards, Richard Harrison, KB5WZI

Hi Ronald

Take a look at my copper cactus at http://archimedes.galilei.com/raiar
it can have one or as many bands as you would like.
There is a K-factoring chart on there for adjustment to any frequency.

As long as you are reading actual on air comparisons, might as well read the great presentations from Mike Banz at:

http://www.qsl.net/aa3rl/titandtl.html

He really helped me know that the GAP Titan DX was the compromise that I needed for my antenna restricted back yard. Very Pleased with 162 countries on 6 bands without radials... Still happy I made the choice.

I don't know what you mean by 'excellent' for ssb. The loops will not have any gain and are not directional. While you can have some fun with the loops, you should be looking at a beam on no less than a 10 foot boom and longer if you can support it. If you can stack 4 of the horizontal loops you may get close to 6 db of gain over a dipole. Not much to brag on when a 3 element beam will give around 8 or 9 db. The beam will usually be easier to build and get working than several loops stacked and phased correctly. If you want to build something , the quagi type might be a good starter project for the antenna. It is a beam with the reflector and driven element made like square loops and the director elements made like a regular beam.

For small pinholes or cuts in the PVC jacket, apply something like Duco cement (or clear Bostik in the UK) which welds to the PVC, and then tape over that before the cement dries.

However, if you find the hole *after* discovering water inside, and if the coax has a braided jacket, the whole length is probably already ruined, from the hole to where the water comes out. You can check by peeling back a little of the jacket and looking at the braid - if it isn't bright and clean, it's no good.

If the coax has a solid copper outer conductor, there will be no problem from holes in the outer jacket because the water cannot corrode the inner surface of the conductor. But there may be a problem at the connector itself, because water can migrate down between the jacket and the outer conductor, and come out into the plug. The cure for that is to cut back the outer jacket, close to the plug, and either let it drain or seal it up with some bare copper showing.

Dealing with electrical contractors have them look at some of the
Scotchfil and 130C type of insulation putty. It should be reconised by
the contractors. Some of it is similar to the coax seal.

There will be some signal loss through the glass. Also, these don't
work well if located within 1 inch or so of ANY conductive material
(including defrosting elements). If it were me, I'd get a decent
Diamond or Comet multi-axis lip mount and use that instead of some
trade-off through the glass setup - but it's your car, your vehicle...

This has been discussed many times, but I'll throw in my $0.02 worth.

I started with the "standard" ARRL sanctioned "ultimate" circuit and used it until I went through the loss calculations for the network. In many areas of the Smith chart, its OK, but when I "discovered" I could load the network into itself so long as I cooled the inductor, I began to wonder what was going on. Do the loss calculations for the network! You won't like what you see.

I now use a differential-T, or twin-T, network with the current balun at the 50-ohm port. Correctly stated by other respondants to this post, the choke balun is FAR more capable of handling the task of assuring balanced current into/out of the conductors of the balanced system. In coming to this solution, I tried several current baluns at the output of a single-ended tuner. Yes, I cracked a very nice ferrite core, and had several designs that resulted in 2" of corona off parts of the balun with only 200 watts (7200' elevation didn't help the situation).

The antenna system consists of a 1200' long "doublet" fed with open wire, mostly through the attic made of #6 "ground" wire on electric fence standoffs. The balun at the 50-ohm port of the tuner consists of 10' of RG-142 high-power teflon coax available from RF Parts and many ham swap meets. There are 24-turns on a toroidal core of 43 material. The core is roughly 4" OD X 1.5" ID X 1.25" thick. At 1 MHz it measures +j400 so its good on 160-meters as well. It self resonates at roughly 47 MHz. If you shop carefully at swap meets and the like, you can build the tuner for about $150 or less. The few commercial units that are available are EXTREMELY expensive for what they are.

If I had to give only ONE piece of advice, it would be: DO NOT PLACE THE (CURRENT) balun at the tuner output (that point is potentially all over the Smith Chart!).

AMATEUR RADIO NEWSLINE(tm) REPORT #1272 - DECEMBER 28 2001

==========

A NOTE TO THOSE WHO ONLY “READ” AMATEUR RADIO NEWSLINE(tm)

For those of you who only know of the Amateur Radio Newsline (tm) as a text newsletter we would like to invite you to listen to the audio version. This Amateur Radio Newsline (tm) script is actually written for the “spoken word.” It is recorded each by professional broadcasters and is available for private listening or rebroadcast over your repeater. Three methods of delivery are available: Streaming audio using RealAudio, FTP RealAudio or dial-in telephone. Please visit our website at http://www.arnewsline.org for a list of telephone numbers (you have to pay your own long distance charges) and links to audio servers providing our voice newscast (for free).

de
The Newsline Production Team

==========

Amateur Radio Newsline report number 1272 with a release date of Friday, December 28th, 2001 to follow in 5-4-3-2-1.

The following is a Q-S-T.

A not so welcome FCC Christmas present for several hams and an ARRL survey says that most hams no longer want the novice bands. These stories are first on this New Years week edition of the Amateur Radio Newsline coming your way right now.

(Billboard Cart Here)

**

ENFORCEMENT: FCC DESIGNATES KEVIN MITNICK, N6NHG, LICENSE RENEWAL APPLICATION TO PUBLIC HEARING

A convicted computer hacker now has to face an FCC if he wants to keep his ham radio license. This, as the regulatory agency designates the Amateur Radio license renewal application of Kevin David Mitnick, N6NHG, for hearing. We have this report:

--

According to the FCC, Kevin David Mitnick is best known to the world as a hacker who admitted that he broke into a number of computer systems and stole proprietary software belonging to Motorola, Novell, Fujitsu, Sun Microsystems and other companies. He has also admitted using a number of means to commit

his crimes including social engineering, cloned cellular phones ad sniffer programs placed on a victims computer system. Mitnick even acknowledged altering the programming of computer systems belonging to the University of Southern California and using these computers to store programs that he had misappropriated.

Mitnick was sentenced to forty six months in federal prison for his August 9th 1999 conviction. He had previously been sentenced to twenty-two months in prison for possessing cloned cellular phones after his arrest in North Carolina in 1995 and for violating his supervised release that had been imposed after his conviction for unrelated computer fraud in 1989. He is currently on probation following his release from prison in January of 2001. And in December of 1999, Kevin David Mitnick, N6NHG, applied for renewal of his Amateur Radio Station and his General Class Operators License.

His license expired on December 12th 1999. The FCC put the renewal application on hold pending further inquiry. Now the agency has made public that it intends to challenge Mitnick's right to hold a ham radio license and has issued a Hearing Designation Order. In plain English, that means Kevin David Mitnick has to prove to the government why it should renew his ham ticket or have his license cancelled.

The FCC is challenging Mitnick's license renewal request on the ground that his past criminal behavior raises a substantial and material question as to whether Mitnick possesses what the it terms as the requisite character qualifications to remain a Commission licensee. The FCC says that in the context of broadcasting licenses, it has long held that evidence of any conviction for misconduct constituting a felony will be considered as relevant to its evaluation of an applicant's character. It also says that the broadcast character qualifications standards have been used as guidelines in the evaluation of non broadcast licenses including those in the Amateur Service and that the courts have upheld the Commission's right to do this.

The agency cites two recent cases. That of Herbert L. Schoenbohm, the ex-KV4FZ and Leslie Brewer who used to be KC4HAZ. Brewer, also known as the Tampa Party Pirate lost his ticket because of his unlicensed broadcasting in the commercial F-M band . Schoenbohm lost his based on a fraud conviction of using an unauthorized telephone access device. And the FCC says that any conviction for fraudulent conduct calls in question a licensee's ability to act in a manner consistent with FCC regulations.

And so the FCC has ordered that a hearing be held before an Administrative Law Judge to determine the effect of the criminal convictions of Kevin David Mitnick on his qualifications to be a Commission licensee. It also says that pursuant to provisions of the Communications Act, the burden will be on Kevin David Mitnick, N6NHG, to provide proof that his license renewal application should be granted. Mitnick was given 20 days of the mailing of the Hearing Designation Order to file a response.

For the Amateur Radio Newsline. I'm Andy Jarema, N6TCQ.

--

The hearing designation order on Mitnick’s license was adopted by the Commission on December 11th but not released until Friday, December 21st. Ironically, less than twenty-four hours earlier, Mitnick had made a guest appearance on Art Bell’s Coast to Coast A-M where he discussed his future plans. At that time he was apparently unaware that the FCC had some plans of its own in regard to whether or not N6NHG will remain a radio amateur and Commission licensee.

The complete text of the Mitnick FCC Hearing Designation Order is on the web at: http://www.fcc.gov/Daily_Releases/Daily_Business/2001/db1221/fcc01359.txt (FCC)

**

ENFORCEMENT: GERRITSON LICENSE PLACED ON HOLD PENDING POSSIBLE HEARING

Kevin Mitnick, N6NHG, is not the only person hearing from the FCC in recent days. So have a number of others including another Southern California resident who could face the same kind of a hearing. Riley Hollingsworth, K4ZDH, is the FCC’s Special Counsel for Amateur Radio Enforcement:

--
Hollingsworth: “We notified a Bell California licensee; Jack Gerritson, ex-KG6IRO, that the Wireless Telecommunications Bureau, had set aside his Technician grant so that a recent conviction for radio interference could be evaluated. Now, he has no authority to operate Amateur Radio equipment until the matter is resolved.”
--

The action to place Gerritson's license up for hearing was taken November 14, 2001 and is based in part upon complaints about the operation of his station and questions regarding Gerritson's qualifications to be a Commission licensee. The FCC says that both issues were raised as the result of Gerritson's 1999 arrest and year 2000 conviction for interference to police radio communications. (FCC)

**

ENFORCEMENT: FCC REOPENS KY-W.VA REPEATER CASE

The FCC is also continuing its crackdown in the area of repeater interference issues. In fact it is taking a second look at a coordinated versus uncoordinated issue in the Tennessee and West Virginia border area. Again, Riley Hollingsworth, K4ZDH:

--
Hollingsworth: “We notified parties in a repeater dispute in West Virginia that we would be reopening that case after information that one of the repeaters is coordinated after all. We had declined to intervene earlier this year in that case.”
--

The letter stating that the FCC is reopening that case went to Michael Horn, KB8GDF, of Lenore West Virginia, Kenneth Brown KF8HL of Davin West Virginia and Carl Tussey, KB4UCE of South Williamson Kentucky. Back on January 24, 2001,

had notified the three that it had received a complaint that they were operating an uncoordinated repeater on 145.390 MHz in Mingo County, West Virginia, and that this repeater was causing interference to the coordinated KC8FKP repeater operated by the Portsmouth Radio Club that uses the same frequency. The matter was closed when the FCC interpreted a notation in the South-Eastern Repeater Associations Repeater Journal that the status of the KC8FKP repeater was not known and interpreted this as meaning that the repeater was also was not coordinated.

But now the FCC says that it has recently come to it's attention that although in the SERA Repeater Journal says that the KC8FKP repeater may be listed as unknown, it is still a coordinated system. Therefore, the FCC is re-opening its review of the issues in this matter. (FCC)

**

ENFORCEMENT: IS A GOVERNMENT AGENCY RUNNING A HAM REPEATER?

Is a government agency operating ham radio repeaters in violation of Part 97 rules? Specifically, the FCC wants to know who is really running the KD6LSO and W6SON repeaters in Sonoma County California.

The FCC says that it has received allegations that the county is in charge not the hams whose call signs appear on the machines. Since a county governmental entity cannot be an Amateur licensee, the FCC is collecting information in order to determine if there are breach of its rules. (FCC)

**

BREAK 1

This is ham radio news coming to you from the United States of America. We are the Amateur Radio Newsline, heard on bulletin stations around the world, including Rocky Mountain Radio League repeaters serving Denver and Bloomfield Colorado.

(5 Sec Pause Here)

**

RESTRUCTURING: ARRL STUDY SAYS NOVICE BANDS MAY NOT BE NEEDED

An ARRL study group has recommended doing away with the current novice bands and divvying them up among the remaining licenses classes. Amateur Radio Newsline's Norm Seeley, KI7UP, has the details:

--

An ARRL Novice Spectrum Study Committee has recommended that the League petition the FCC to eliminate the CW novice subbands. It also wants a rules change that will allow Novice and Technician licensees with element 1 credit to be permitted to operate Morse code on the General 80, 40, 15 and 10 meter C-W allocations at up to 200 watts power out.

These are just two of the suggestions contained in a report that will be presented to the Leagues Board of Directors when that group convenes in mid January. The study committee will also suggest recognizing portions of the 80, 40, 15 and 10 meter Morse bands for what it calls ''slow CW operation.'' The committee says that this would aid new operators in enhancing their Morse code skills.

Finally, the panel also recommends re-farming -- that’s another way of saying reapportioning -- reapportioning the current Novice and Tech Plus subbands in part. This, to allow expansion of the phone allocations on 80, 40 and 15 meters.

What will the ARRL Board of Directors do? We should know in less then a month.

For the Amateur Radio Newsline, I’m Norm Seeley, KI7UP

--

The committee's determinations were based on opinions expressed by 4744 hams who respond to an ARRL Novice Spectrum Study survey launched last June. Those expressing their opinions included ARRL members and also non-members. What’s really interesting is that nearly 61% of those responding were Extra class licensees. (ARRL bulletin)

FCC INSPECTOR GENERAL'S REPORT: THE NAMES THE SAME

The latest report of the FCC's Office of the Inspector General contained very few items of intrigue. But according to the C-G-C Communicator, one of the more colorful incidents involved a person who allegedly used the name of an FCC employee to obtain the government-rate for a hotel room in conjunction with a government-sponsored event.

Well, it turns out that the subject was legitimately attending the event, was entitled to the government room rate and just happened to have the same name as the FCC employee. The bottom line: Case dismissed.

The complete report is on the FCC website at http://www.fcc.gov/oig/Semiannual093001-1101.pdf (CGC Communicator)

AMERICA AT WAR: NYC PHONE SERVICE STILL SPOTTY

It's been almost four months since the attack on the World Trade Center, and telephone service near ground zero in lower Manhattan is anything but normal.

According to news reports, repair people have restored service to most customers, but thousands of lines still aren't working. As a result, customers complain that some business lines can call out, but customers can't call in.

The collapse of Seven World Trade Center crushed thousands of underground cables at Verizon's nearby switching station. About 200-thousand telephone lines and three-point-five million data circuits were affected. The company says it'll spend as much as one-point-nine billion dollars to repair the

damage. (Telecommunications Online)

**

INTERNET SECURITY: PROBLEMS WITH XP

If you just bought a new computer equipped with the Microsoft X-P operating system, or have upgraded your old one, listen up. The Federal Bureau of Investigation says that you should take certain steps to protect yourself against hackers who might try to take advantage of major flaws that have been found in X-P.

The bureau's National Infrastructure Protection Center says that in addition to installing a free software fix offered by Microsoft on the company's Web site, consumers and corporations using Windows XP should disable the product's universal plug and play features as well. The FBI also warned computer system administrators to actively monitor for specific types of Internet traffic that might indicate an attack was under way.

The FBI did not provide detailed instructions how to disable plug and play. Outside experts also caution that disabling the affected Windows XP features threatens to render unusable an entire category of high-tech devices about to go on the market. This includes a new class of computer printers that are easier to set up. But the same experts also acknowledge that disabling plug and play in X-P could afford some protection against similar flaws discovered in the future.

Microsoft considers disabling plug and play options as being unnecessary but the company does acknowledge that Windows X-P suffers from serious problems that can let hackers steal or destroy data files across the Internet or implant their own unwanted software. The FBI says that the glitches were unusually serious because they allow hackers to seize control of all Windows X-P operating system software without requiring a computer user to do anything except connect to the Internet. (Published news reports)

**

THE LAW: A FIGHT AGAINST GRAY MARKET ELECTRONICS

A group of American high-tech companies is opening the year 2002 with a campaign to protect consumers from unwittingly buying consumer electronic products intended for foreign markets. Electronics that the manufacturers claim may not work in the United States.

Compaq Computer is one of the companies involved in the campaign. It says that the group will warn consumers about the dangers of buying such products, and how to avoid getting duped. The other companies in the group are Hewlett-Packard, 3 Com, Nortel Networks, and Xerox. The effort may prompt more lawsuits against distributors who resell so called gray market items in the United States. (Computer Products Daily)

**

SPECIAL EVENTS: USS ARIZONA K7A A SUCCESS

Steve Gurley, KJ7WK the coordinator of the USS Arizona Special Events Station K7A tells the Amateur Radio Newsline that the event was an overwhelming success. Gurley says that the memorial station contacted amateurs in all 50 states, and 8 other countries while handling over 2600 QSO's. In fact says KJ7WK, the sponsoring group has already received certificate requests from 609 stations as we go to air. There were ten operators in three counties in the Phoenix Arizona metroplex operational during most of the three days K7A was on the air. (KJ7WK)

**

SCHOLARSHIPS: DARA SCHOLARSHIPS FOR 2002

The Dayton Amateur Radio Association says that the nominating period for its annual scholarship program is now open. The deadline to receive applications is June 1, 2002 and the announcement of winners will occur around June 15, 2002. Applications are available from the DARA Scholarship Committee, 9873 Lower Valley Pike, Medway, Ohio 45341. Please note that this is a new address from years past. Again it is the DARA Scholarship Committee, 9873 Lower Valley Pike, Medway, Ohio 45341. Also, for more information on the Dayton Amateur Radio Association and its programs, please visit www.dara-w8bi.com on the world wide web. (DARA)

**

AWARDS: DARA OPENS NOMINATIONS FOR HAM OF THE YEAR

The Dayton Amateur Radio Association also asks that we remind you that the nominating period for the 2002 Dayton Hamvention Awards is now open. There are three awards presented each year. They are the Radio Amateur of the Year, Special Achievement, and Technical Excellence.

All amateurs Novice through Extra are eligible. Awards are decided by the Awards Committee, based partially upon the information received. Magazine articles, newsletters, newspaper clippings, videos and the like are appreciated but cannot be returned. The deadline for nominations is January 31, 2002. Nominations should be sent to Post Office Box 964, Dayton Ohio 45401. They can also be submitted by completing the e-form on the web at www.hamvention.org. (DARA)

CHANGING OF THE GUARD: BADGER STATE SMOKE SIGNALS EDITOR JIM ROMALFANGER, K9ZZ - SK

I’m Bill Pasternak, WA6ITF.

The ham who put the state of Wisconsin on the ham radio map has passed away. This, with word that Jim Romelfanger, K9ZZ died Saturday evening December 22nd of an apparent heart attack..

According to Romalfanger's close friend Ken Ebneter, K9EN, Jim has been in declining health for some time. Romalfanger had a stroke a few weeks ago, affecting his right arm which was already weakened by polio. But Ebneter says that K9ZZ seemed to be improving until just recently. Ebneter says that Romalfanger had been in the hospital early last week but was home when he passed away of an apparent heart attack. In fact, K9ZZ had stopped by to visit a ham radio friend that afternoon. Another friend found him dead that evening when he stopped by to visit.

His full name was Arthur James Louis Romelfanger but to the world of ham radio he was Jim, K9ZZ. And Jim Romalfanger made Wisconsin a ham radio household word by editing as three decade state-wide ham radio monthly newspaper called Badger State Smoke Signals -- and doing so as a volunteer.

Notice we said newspaper and not newsletter. This is because Smoke Signals is just that. A newspaper that at its peak ran up to 40 pages filled with articles about ham radio in the Badger State. In addition to being the 32 year editor of Smoke Signals, Romalfanger was nationally published over the years in CQ, QST, 73, Ham Radio, Popular Electronics, and other magazines.

Jim Romalfanger was first licensed January 1958 in Pacific Beach, California, as KN6LWB. Upgraded to General in May of 1958. He returned to Wisconsin that summer and became K9PKQ. In 1977, changed call to K9ZZ and held that call sign the rest of his life. Funeral services were scheduled for Friday, December 27th at St. Joseph Catholic Church in Baraboo Wisconsin.

Jim, from all of your friends at the Amateur Radio Newsline: We are going to miss you. (The Baraboo News Republic, K9EN, WB9QZB, and other friends of K9ZZ contributed to this report.)

AMAZING DISCOVERIES: CIRCLES WITHIN A CIRCLE

One of the most curious pure mathematical discoveries for 2001 was announced in the easy-to-read article at an incredibly long website. In brief the article says that research has led to some remarkable geometric findings involving interrelationships between tangent circles and spheres. In other words, mysterious circles within a circle.

As one researcher put it, "Where do these numbers come from? What's going on here?" Find out by going to www.sciencenews.org/20010421/bob18.asp (CGC Communicator)

INTERENATIONAL - CANADA: NEW ALBERTA SM

On the international front, word that Thomas Martens, VE6TRM, has been appointed the new Radio Amateurs of Canada Section Manager for the province of Alberta and the North West Territories. Martens replaces Alan Faint VE6QQ will

be stepping down from the position due to personal reasons. Martens will serve the remainder of Faint’s term which runs through June 30th, 2003. (RAC)

**

INTERNATIONAL-AUSTRALIA: CSIRO MICROTURBINES

Australian hospitals, restaurants and schools could soon source clean, reliable energy from mini power generators that operate independent of the main grid. This as CSIRO has installed Australia's first commercial microturbine, at their North Ryde Laboratory, Sydney.

The size of a small refrigerator, the turbine produces 30 kilowatts of power, independent of the electricity grid. And it does this with reduced greenhouse and other gas emissions. Thirty kilowatts is enough to power a medium commercial building such as a restaurant.

Along with fuel cells, gas engines, storage technologies and some renewable technologies, microturbines can be used to generate power close to the end-user and provide major gains in reliability and power quality. Once the design can trickle down to the home user level and price range, it could offer hams a way of always having emergency power always at hand. (Q-News)

**

SHORTWAVE MONITORING : RADIO NORWAY CLOSES

The Board of Directors of the Norwegian Broadcasting Corporation has decided to stop its own programs by Radio Norway International. This is effective as of December 31st of 2001.

According to DF5SX and G3VGW, Radio Norway’s final show was hosted by veteran broadcaster Einar Lie on New Years Eve. Also, the 1200 kilowatt Medium Wave transmitter on 1314 kHz on Kvitsoy was supposed to cease operation by December the 31st as well.

The Norwegian Broadcasting Corporation will have to negotiate with transmitter providers Norkring and Radio Denmark to close down as well. The Norwegian Broadcasting Corporation and Norkring have a contract for running the transmissions that goes through December 31st, 2003. The agency also has a leasing agreement with Radio Denmark for the same period. (Media Network)

DX

In D-X, keep an ear open for King George Island in the South Shetland group. HFZ0POL is reported on all H-F bands, including the newer ones, using CW, SSB, RTTY and PSK31. QSL HF0POL via SQ5TA.

And the United Arab Emerates has been heard lately A61AJ. He has been QRV on 40 meters CW around 1400 UTC. Q-S-L A61AJ via N4QB. (Various DX sources)

**

THAT FINAL ITEM: RILEY SAYS THANKS

And finally as the year 2001 comes to an end, the FCC’s Chief Rules enforcer, Riley Hollingsworth has some words of praise for the ham radio community. He passed them along through his bi-weekly Enforcement Log at www.rainreport.com, and thanks to them, we have is words for you:

--
Hollingsworth: “I would like to point out Hap, that this is the end of the third year of Amateur Radio enforcement and I will honestly say that the overall level of compliance in the Amateur Radio Service is outstanding. The Amateur licensees do a great job and they do a great job of showing that the Amateur Radio Service is -- indeed -- the only fail-safe communications system in the world and we are very proud of them.”
--

And if I can take off my reporters hat for a moment and editorialize a bit, I guess I speak for many who truly appreciate what you have done to return the Amateur Radio bands to the law abiding members of the nations ham radio community. (ARNewsline(tm), RAIN)

Cross-posted to: rec.radio.swap,rec.radio.amateur.antenna,alt.ham-radio.marketplace

For sale...

Tri-Ex TM-358 Sky Needle tower. Includes 58' three section tubular tower, newly recabled with SS cable, 10' thickwall mast, complete motor assembly for controlled extension and retraction, CDR sized rotator cage assembly, new hinged base, instruction manuals, a 1997 UBC stress analysis, blueprints, and even the side mounted ladder!!!...the whole enchilada ready to
grace your property.

Tower is down and next to my home. It is HEAVY (on the order of 1500#), so it will take a wrecker or 15 very strong men to lift it out of the yard and onto your car trailer.
To install you will need to manufacture or purchase the re-bar assembly that goes into
the hole, gather up the gears and thrust bearings for the rotator assembly, and lots of labor!! This is not one of those lightweight and flimsy tubular towers!

This is the cadillac of tubular towers. Very strong and rated at 12.4 square feet at 60mph, 7.2
square feet at 78mph, and 3.6 square feet at 95mph while fully extended!! Dead weight capability is 400# including rotor and rotor cage.

Start your new year with a REAL tower that can actually handle realistic antenna loads
yet still be asthetically pleasing to your neighbors.

Pictures available upon request. Email your questions or interest to paul@dock.net

$2495.00 cash, cashiers check, postal money orders all OK.

Located in Thousand Oaks, CA (45 miles NW of LAX).

>Where do you place your two baluns? Is there one each before and after your
>tuner, or what?

After the tuner. I got 2 of the balun kits, so instead of a 50 bead choke balun, I have a 100 bead. Its been suggested that to have enough choking impedance 150 or 200 are even better. 100 seems to work for me.

Thanks for the many responses. I have concluded from reading them that a low cost, yet effective solution is to replace the 4:1 balun with a Model BA-8 1:1 choke balun kit from Paolmar Engineers for $15.00. See http://www.palomar-engineers.com/Balun_Kits/balun_kits.html for details. It's not clear to me that spending $1000 for a couple of roller coils and capacitors would improve my situation that much.

>>A balanced antenna fed with a true transmission line should not care about
>>tuner type.
>
>It certainly does!

Of course it does, not sure what I was thinking. Say Tom, what is the preferred way (for a Ham) to check that the currents are balanced in an open wire feed line? I made a relative rf ammeter using a Radio Shack snap on ferrite core. It is fairly sensitive, I can get a usable reading exciting my system with a mfj 259b. I take the reading on one conductor and then move to the other and compare. On 40 it says I am balanced within 3%. Is this good or bad?

As someone mentioned early on you'll get lots of opinions....here's mine---I used the Larsen dual-bander on both my XYL's car and my truck and they work just fine. Granted they aren't optimal and won't perform as well as a dedicated, drill a hole in the roof, antenna but if you understand that going in and it meets your communications needs then by all means it is A way (not the only way) to go.

Hello,
I have this coaxial cable that has 100Mbps Ethernet Manchester encoded signal (then 200 Mhz ?) for computer networks.

The problem is that I have to go through this ~6 inch brick wall but, I do not want to spend more money on wireless LAN equipments nor I do not want to put a hole through this brick wall.

Would it be possible to come up with some kind of patch antenna that can be put on both side of the wall and Tx/Rx the signal through.

Or am I dreaming ?

Thank you very much.

No chart needed. It's a simple height to distance ratio. I'm not
sure exactly but it's something like 200:1 or 100:1.

In other words, if you are 2000 feet from the airport you can go up
100 feet. With a maximum of 170 feet.

Actually, this is one of the items we all studied to get our ham
licenses. It's been 35 years since I took the test though.

All this pertains to a tower not painted and lit according to FAA
regulations. If you want to do the paperwork and painting and
lighting, you can do a lot. I work at a TV station that has a 591
foot tower that is less than 100 yards from an airport runway. There
are hangars and planes parked underneath the guy wires.

My current balun always sees a resistive impedance between 25 ohms
and 100 ohms with no tuner needed. Check out my web page to see how.

Cross-posted to: rec.sport.billiard,rec.radio.amateur.antenna,rec.arts.books.tolkien,rec.drugs.smart

The safety and serenity of Alaska provided an atmosphere conducive to deprogramming, despite the pandemonium that ensued. Mark Phillips was the first man who not only did not abuse us, but cared for our welfare and well being. His patient, gentle manner was therapeutic, while his propensity for handling weapons and apparent intellect kept us safe against all odds. Through his noble actions, Mark taught Kelly and me that the world of human interaction in which we had existed for so long was contrary to most human behavior. We learned that goodness does exist on this Earth, and that there were those in Washington, D.C. who refused to tolerate the mind-control atrocities they witnessed us and others enduring.

As my eyes opened and I woke up to reality, I became enraged. Enraged for the traumas inflicted on my daughter. Enraged for a lifetime of abuse at the hands of our country's so called "leaders". Enraged that the American public had no idea as to who and what was/is running their country. Mark helped me refocus my rage in a productive direction when he told me, "The best revenge is total recovery."

I began recovering at the rate of 18 hours a day through intensive therapy destined to restore my memory and, ultimately, my mind. I learned the ins and outs of my own mind and recovered my memories in a journal. The stack of journals grew as over a decade of White House/ Pentagon-level abuse flooded my mind and intruded on my thoughts. Pictures from my past flashed across my mind as neuron pathways opened in my brain. I was regaining access to my own mind and control over my future by recovering my memory of my past.

Best of all, I was falling deeply in love with Mark Phillips. Why wouldn't I fall in love? He rescued my daughter and me from certain demise, restored my free will, and was helping me recover in total safety, and was the polar opposite of my abusers. He treated me with love, respect, and thoughtful consideration . Equally as important, Mark proved to be an ideal father figure to Kelly. He provided here with unconditional love and deep understanding. Through him, Kelly caught a glimpse of how kind men could be--and how good life could be. I had long since ceased to know that such a man even existed.

The love factor in my recovery is considerable. Not only did Mark Phillips save my life, but now I had a reason to live it! The love we share kept me going at times--like when Kelly was institutionalized in 1989 for homicidal/suicidal behavior. The loving relationship that Mark shared with Kelly during our short year together as a family was sufficient to arm here with the strength to survive her ensuing ordeal

as a victim of the so-called mental health and criminal justice system.

Kelly, now 15, remains a political prisoner in the custody of the State of Tennessee where she is denied qualified therapy for the MK-Ultra Project Monarch Mind-Control abuses she endured. The state of Tennessee, under the politically powerful influence of Kelly's abusers, is in violation of numerous laws and basic civil rights in their determined efforts to keep Kelly from qualified therapy and the family she loves.

While many of those in positions to make a difference in Kelly's case operate on a "Need to Know" basis rather than deliberately conspire with the bad guys, a closer look into Kelly's case history should raise serious questions in their minds. Questions like; "What could a child have to do with the so called "National Security" of our country?" The Juvenile court judge presiding over Kelly's case closed the doors to the media and onlookers for "reasons of National Security" while gross and blatant violations of laws and rights ensued.

For over three long years, Kelly and I have been denied our right to an unbiased attorney while court-appointed advocates and so-called "guardians" join forces with attorneys paid off by me pedophile father. My own court-appointed attorney, who doubles for the Juvenile Court judge when he takes a day off, has yet to represent my interest. My interest is in Kelly's well being and future-- and if she will have a future at all.

While Kelly is still amnesic with regard to most of her past, she is deliberately denied therapeutical access to her past, due to who and what she will recall. I am denied access to Kelly for fear she would be triggered into remembering by my mere presence. As for my deliberately "triggering" Kelly to remember what she was supposed to forget, as her abusers fear, it has been my experience that recovery must come from the inside out. Not from outside input. I want no less for Kelly that the piece/peace of mind I have gained through qualified rehabilitation. Which raises the questions: Why has the Juvenile court prohibited us from saying the name "George Bush?" Why is the "Wizard of Oz" a taboo subject for Kelly while the State of Tennessee provides her with Stephen King horror novels? Why are Kelly and I forbidden by the court to say the words "President," "politics," New World Order", and "mind-control"?.

In an attempt by state employees to "normalize" our relationship, Kelly and I are forbidden to discuss the past, my immediate efforts to affect her dire and desperate situation, or future plans as a family.

Most appalling and unjust in Kelly's view is the State of Tennessee's refusal to allow her any contact whatsoever with Mark Phillips. While I am hindered from having private conversations with my daughter due to court ordered supervisions and censorship, Kelly is denied the right to even wave to Mark across the parking lot. Considering that, like me,

Mark has never been named as an abuser, declared unfit, or violated any court orders, the questions must be asked: "Why does the State of Tennessee go to such lengths to ban all communication between Kelly and the man who rescued her and taught her the meaning of unconditional love?"

Kelly has asked these questions for years to no avail. The State of Tennessee refuses to even acknowledge her request for"an unbiased attorney who will represent her interests instead of those of the state". Kelly's pleas for an attorney to represent her go no farther than the deaf ears of the assigned state social worker "managing" her case. This social worker is operating on a "Need to Know" basis that has no basis, and she "Needs to Know" that she, along with the State of Tennessee, will be held accountable in the event that Kelly hurts someone or herself.

Kelly's frustrations have mounted beyond her ability to cope. I applaud Kelly for her determined but weakened efforts to stay in control of her own mind despite being denied qualified rehabilitation for the devastating results of Project Monarch Mind-Control abuses. Kelly's daily attempts to accomplish the impossible by psychoLOGICALLY managing her psychiatric disorder is proportionate to her high intellect and willful determination. But it is not enough to fend off the Psychological Warfare that has been waged against her through CIA Damage Containment practices designed to keep her contained in amnesic silence. She needs help. She needs a collective voice.

Kelly can be helped through public outcry and through abolishment of the 1947 National Security Act (and 1984 Reagan Amendment to same) that has destroyed the true security of our once great nation. You can write the State of Tennessee demanding to know why Kelly is being denied her right to qualified rehabilitation.

Thank you. - Cathy O'Brien

Every submitted comment of encouragement will be greatly appreciated!

Source record: 152114

See FAA - AC 70/7460.2K

Two cases:
Airport with runways longer than 3200 feet: Out to 20,000 feet (almost 4 miles) away,
Slope of 100:1, and 2000 feet away would permit a height of 20 feet, not the 100 someone else suggested.

Second case: If the runways are less than 3200 feet, out to 10,000 feet, slope of 50:1, for the 2000 foot example, antenna height no more than 40 feet.

Hopefully somebdy can help me with this one quick before I fall off my tower into a snow bank!

There was some remodeling done in my room where my rotot box was once hooked to my Alliance HD73. Problem is, the wires were removed from the control box without being marked.

So, here is the good part, I broke down, in 20 degree weather, with snow flying, wind blowing, I climbed to the 30 foot height and opened up the rotor wire cover to see what wires went where.

Here is the part I couldn't totally confirm for sure, I could only see a number "2" mark on one terminal connection.

So, here is the terminal connections as if the rotor was oriented as it were mounted in a tower and you where standing on the ground looking at it:

A 2 C
X X X

X X X
D E F

The "X"'s represent the terminal hookups. The letters represent the terminal (number) hookups in question. The "2" was the only terminal I could confirm.

So, the question is, which terminal is which number?

My rotor is the latest model, the HD-73-1, I believe its called. I found the manual online (ftp://bama.sbc.edu/downloads/alliance/hd-73/) - but it was for the HD-73. I went to the troubleshooting section and found where it tells you was resistance to look for between the wires to help straighten out which wire is which. All the resistance values checked out except the last note on the troubleshooting section where it says "Also, leads 1,3, and 6 should not show continuity to leads 2,4, or 5"

I see a some resistance between all combinations of these leads they state should show "no continuity" (open?)

Help, please!

Scott.

4722. Re: What is a good 5 band vertical? Gap??

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-29 01:05:26 UTC
From: Mike <km6ab@pacbell.net>
Message-ID: <3C2D16DA.57D28EE9@pacbell.net>
Source record: 151974

I had a GAP Titan. It went together fairly easy, had a respectable match on all bands, but then most dummy loads do. It did seem to work ok until I compared it to other antennas like an SGC autotuner and random wire, a 40m dipole fed with ladder line with a tuner at the radio and a G5RV. The Titan was a very poor performer on all bands compared with what I thought were mediocre antennas. Even local 10m vertical polarized contacts came in better with a 30ft horizontal wire and an SGC tuner. Most of the antennas I used for comparison were less than 25ft off the ground (cloud burners) and they still outperformed the Titan on DX. I was a little suspicious when the GAP salesman at Dayton was claiming fantastic gain over some of the other popular verticals like Cushcraft R7000 and I'm a little embarrassed I fell for it. He would have made a great used car salesman. (no offense to any used car salesman hams please) If someone is singing praises about an antenna I usually ask "compared to what?" The answer is usually "well, its my first and only antenna".

4723. Re: Water in coax

Newsgroup: rec.radio.amateur.antenna

Thanks for all the tips. I will be upgrading the antenna Saturday, and I have decided to cover the conduit head (where conduit goes in the ground to the house/shack) with a plastic bag to keep it and the splices from getting rained on. Also am going to see if I can make a cover (from a Dannon Yogurt container - the large one about the size of a coffee can) for the feedpoint of the inverted vee. I figure I can suspend it on the support rope so it acts like an umbrella over the center insulator/coax attachment point.
You guys have convinced me of the futility of easily waterproofing a coax connector, so I am going to try this. Maybe I can report back in the spring how it worked.
Thanks again, 73,
Rick K2XT

>bad?

You really need to clamp the meter around BOTH conductors at the same
time, and excite the feedline normally through the tuner. That way you
will read actual common mode current.

The method you described doesn't mean anything, because almost any
line with high mutual coupling between wires will read the same
impedance and current. It not only does not account for the actual
feed method, it also does not indicate phase errors.

To be balanced, currents have to be equal and exactly out-of-phase in
each conductor. Clamping a good meter over both conductors at the same
time will tell you if the current and phase is correct, by the meter
reading very low compared to the current reading over each individual
conductor.

73 Tom

>Do the loss calculations for the network! You won't like what you see.

Been there and done that, and the loss is NOT that bad. It takes a
terrible inductor to act ike a dummy load. If it does, the inductior
would melt down even at low power, like 50 watts or so RF.

Loss is worse when the load impedance is near zero, and/or very
capacitive. Loss is minimal when the load impedance is moderate or
high, and with inductive loads.

>I now use a differential-T, or twin-T, network with the current balun at the
>50-ohm port. Correctly stated by other respondants to this post, the choke
>balun is FAR more capable of handling the task of assuring balanced current
>into/out of the conductors of the balanced system.

That simply is not correct. Moving the balun to the 50 ohm port does
not change the common mode stress on the choke balun any significant
amount because the network does not transform the common-mode
impedance.

The exception would be if the network was balanced and ground
referenced at the middle of the network, like a pair of T networks
inthe form of an "H" with the center of the "H" grounded.

In any case loss in the matching components is exactly the same no
matter where the balun is, as long as Q and components are the same.

>73, Mont - K0YCN

You are correct Mont, it would be a waste of money and time to go to a
"floating" network with a balun on the input.

As long as the Palomar balun is a good choke balun and properly
designed, it would be the best option.

To be a good balun in this application it should have well-insulated
wires, and a very high common-mode impedance. That normally requires
thick insulation like teflon wires, perhaps 15 or twenty bifilar
turns, and a stack of moderately high mu cores (like 61 or 65
material) cores that are reasonable in size. If the balun uses a
powdered iron core, and enameled wire, stay away from it!

By the way..... I used this type of balun described with traditional
T networks here to replace all my old KW matchboxes. I can not only
match the antennas on wider frequency ranges (wider impedance ranges)
, balance is actually better and power handling improved. All my
matchboxes are now retired in the barn.

Hi,

i love to listen to short wave radio and the antenna i use is a 2 metre wire turned into a coil and suspended from the ceiling! i do get good reception. i am a complete novice concerning antennas,reception and wave propagation. is there a web site where there are such information for a layman like me. Thanks.

Also i am looking for TV antennas that caters for both VHF and UHF reception. The antennas should possess a reflector. Any online catalogue would be very nice and the antenna should not be expensive as there is quite some taxes to pay if i'll buy it.

Thanks a lot fro your kind help.

Rick, K2XT wrote:
"You guys have convinced me of the futility of easily waterproofing a coax connector, so I am going to try this (Dannon Yogurt container cover)."

Rick is too easily intimidated by a bunch of "Nervous Nellies". I know of hundreds of successfully protected coax connectors outside in all weather conditions which have survived for decades while keeping out the water. These are commercial installations. Electrician`s rubber tape is the secret. It keeps connections dry as dust when properly applied and protected itself.

The dannon Yogurt container is questionable. Many plastics are durable indoors but crumble on short exposure to full sunlight. The jacket used on coax is an exception not the rule for plastics.

Thank you all for your input re. my questions on the W7FG Doublet antenna. I ordered one as it was relatively inexpensive. I received it yesterday and I was pleased with the quality of it's construction. I'll be tinkering with many wire antennas in the upcoming months. (Or years...isn't this what it's all about?) I'll likely put up some dipoles and that Carolina Windom 80 too.

I was wondering though. Is there any big difference between using #16 wire as opposed to #14? You see, the Doublet consists of the ladder-line which uses insulated #16 wire that runs unbroken to the center-insulator straight to the end-insulator. So each side is and unbroken length of #16 wire with no solder connections between tuner/balun and end-insulator. Most articles on wire antennas recommend 12# or 14# wire for the actual element. If I'm asking any foolish questions, please be patient with me. (& kind :-)) Thanks and happy holidays to all.

We used to drill drain holes at the bottom of the drip loop outside the equipment building so the water stayed outside instead of wetting down the floor(commercial installation with 350 ft tower and large diameter hardlines.)

Rick hasn't told us if he is now referring to a commercial dipole
connector gadget or simply splaying wires out of coax to make a dipole
connection or if we are just talking about splices in general.
Some connections are a real b**ch to seal up. Bishop
tape/Scotchkote/real 3M 66 splicers tape/splicers putty all have their
weak points. Scotchkote simply cracks, 49 cent electrical tape simply
doesn't adhere well, RTV may fail to adhere and so forth. There's no
panacea in sealing connectors and if a "My God It Looks Like Butter" tub
has to be put over the connection annually, it will probably be worth
the effort no matter how well you think you have sealed the joint.
Not necessarily the best way, but 'a' way.

Wind the coil with 2 or 3 wires in parallel. Remove the un needed
windings after winding is complete and well secured.

Any hardware store can thread a piece of pvc up to 2" with 8 TPI pipe
thread.
14 wire will wind in these threads and be spaced about right.

This makes a good coil for a screwdriver antenna.

It will in this fire district and in most others. sure,
a hole can be put in a firewall, if done correctly, which is
not a job for an amateur. Any such 'do it yourself' project
needs to be 're-thought' before you jump off into it. And
you can take my word for it that a 1/4" or 1/2" hole can
certainly
compromise a firewall. Been there, done that, got the 'pension'
to prove it...

Bert,
There is no practical difference between #16 or #14
wire for antennas. Wire diameter makes absolutely no
difference at HF. If the wire is large enough to hold
up it's own weight (and the feed line, maybe), it's big
enough. A #16 wire antenna will last as long as any of
them will, 'take' as much power, and weigh less. There's
also no great benefit from not making 'joints' between
a feedline and antenna. If the connection is mechanically
and electrically sound, you'll never know it's there.

The whole deal sounds like an expensive way to buy wire. The guage size will
determine breaking strength more than anything else. Most web type ladder
line is 18 or 16 ga anyway so don't worry about the antenna unless it breaks
a lot.
The Carolina Windom will be easier to match with your tuner than that
doublet but will radiate no better and possible exibit more signal loss in
the coax feed line.

Cross-posted to: comp.home.automation,rec.radio.amateur.antenna

First, for human safety and required by the code, a water pipe must be bonded to the electric ground. Ideally (but not necessary for human safety), that water pipe connection is made as close to where the pipe enters earth with no lead solder or mechanical joints. But the water pipe must be bonded to the breaker box ground - by code.

The problem. Assume lightning hits the AC electric line. A surge enters the building, but maybe sees a better ground on the water pipe. How does it get there? Up the electric, through your appliances, then down to the water pipe ground via coax or CAT 5 cable. The complete circuit path put your appliances within an incoming and outgoing surge circuit. Damage results.

Water pipe and breaker box must be bonded. No way around that NEC requirement. How you bond the two could make both act more like a single point ground. One way is to trench a bare copper wire from the electric ground to the water pipe. NEC has specific requirements for the wire size, trench location, and trench depth. Not only would water and electric be bonded, but the interconnecting wire would make both grounds superior. It would also make the earth outside the building electrically more monolithic. All contributing to improved surge protection as well as human safety.

If bonding is made by interior wire, then best to install that wire away from any other household wires and so as to meet the requirements of short as possible, no sharp bends, no splices, not through any metallic conduit, etc.

My best recommendation is the buried interconnecting ground wire. Water pipe and breaker box must be bonded.

Someone once told me that a voltage balun works best where it is not
needed - e.g. when the feedline impedance matches that of the antenna.

Yep. Almost as good is the sealing mastic, such as Ply-seal (tm) or
Vapor-wrap (tm) in place of the rubber tape. But the rubber tape
is much more convenient except for really odd shaped connections.

I have never doped my connectons. The layer of vinyl/Polyethylene over
the top has been sufficient.

They are used all the time commercially. The extra space just has to
be plugged with permitted material - usually a rather soft foam.

You are correct, but like the merchants I just said db and left out the i. Also maybe I should have added in the ground reflection that one of the vhf merchants use and get about 6 more db.. The whole point was that a small beam is easier to construct and match than it is to build and phase several horizontal loops. Especially for a beginner.

How do outlet boxes differ from a 1/4" hole. Each is not airtight,
outlet boxes even less
so. Since outlet boxes are required every so often firewall or not. Code,
NEC, specifies
specific outlet box spacing to avoid the use of extension cords which
account for more fires
than probably any other cause, the exception being space heaters and fossil
fuel area heaters.
Besides a concrete/ brick firewall would divide clusters of units in
apartments/condo's. I really doubt the op was going to run coax/cat 5 into
the neighbors unit.

Dave VanHorn wrote:
"A CB SWR meter won`t work at UHF though,--."

Dave notes that there is a $50 RS meter that works probably well enough.

You may also be able to borrow a Bird wattmeter. They have a slug to cover any frequency in the UHF range.

The coaxial slotted (trough) line also is practical at UHF to determine VSWR directly. You might borrow one of those. My PRD is designed for 1-GHz to 4-GHz. The slot is 10 in. (25.4 cm) long. As the wavelength at 1-GHz is 30 cm, and the distance between minima and maxima is 1/4-wavelength, this PRD slotted line is good at frequencies slightly below 1-GHz. Whatever slotted line you might be able to borrow, its length will be proportional to wavelength, similar to my PRD.

Interesting. In this area a ground rod is required for the breaker box.
The
Cu pipe is bonded to the box as well, however it certainly isn't for
lightning
protection. My "water pipes" exiting the house are PVC. Relying on
"water pipes" for a good lightning ground is a mistake.

I've found that baluns work best when the antenna system is fed at a
current maximum point on the transmission line. My measurements show
that common-mode currents increase on both sides of the current
maximum point.

4770. radials and vertical antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-29 17:36:33 UTC
From: wf3h@ptd.net
Message-ID: <3c2dfe87.235944869@news.ptdprolog.net>
Source record: 151923

Article in most recent QST says those who put in miles of radials against a vertical are wasting their time. States that, once you've balanced the current with 1/4 wave radials (4 or so), you can't reduce ground losses by stringing out more radials.

Since I know many very good EE's who put in miles of radials, makes me wonder what's going on here (I'm not an EE and don't even play one on TV).

Opinions?

"This difference between liberalism and conservatism must not be obscured by the fact that in the United States it is still possible to defend individual liberty by defending long-established institutions. To the liberal they are valuable not mainly because they are long established or because they are American but because they correspond to the ideals which he cherishes."

Source record: 151924

Tony Levand wrote:
>
> What happens when a folded dipole is fed off center? What is the feed
> impedance vs position?

The feedpoint impedance increases from the center to the end. Take a
look at the current distribution (maximum in center, minimum at ends)
and the voltage distribution (minimum in center, maximum at ends).
Dividing the voltage by the current at any point yields the
feedpoint impedance.

One of the disadvantages of off center feeding a dipole is that
it unbalances the antenna currents causing the feedline to
radiate and the radiation pattern to be asymmetrical compared
to a center fed dipole.

I don't have QST . Is this for radials above ground or in the ground ?
If above gound then fine. If radials are below gound then not so fine.

I use one from M2 on my truck, along with 150 watts and have no problem talking to bases with horizonal beams a few hundred miles away. A horizontal beam for the base will work better if you don't need to hear in all directions at the same time.

4777. VHF-UHF-Microwave Log Periodic design question...

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-29 20:18:48 UTC
From: sjnoll@big-list.com
Message-ID: <3c2e2284.11576118@nntp.ix.netcom.com>
Source record: 151930

I'm using lpcad v2.711 to design a log for 110 MHz-2260 MHz.
I was planning on using 1/2" (0.625" OD) copper tubing for the
"feedline" booms. With the characteristic feedline Z being 200 ohms
this results in a center-to-center feedline spacing of 1.7" to feed
with 50 ohm coax. As the front element is only 2" long it seems
weird that the 1" halves of that element will be skewed 1.7" apart
from being co-axial? Am I looking at/doing something wrong here?

TNX,

WA6EJO

Hi:

Thanks for your response. Let me say that I have assumed that the incoming water pipe is not grounded to the breaker box ground. But the place is 10 years old. It is also finished construction in the basement, so it's really difficult to tell if the two are electrically bonded. I suppose I could meter from the water pipe to breaker box ground, but I'm not convinced that a low resistance reading would confirm that a solid electrical connection is present, rather it could mean that the ground rod is driven into earth near the underground water pipe.

> circuit. Damage results.

Right. Without electrical bonding, a ground loop results.

For the sake of argument, let's assume that the incoming water pipe is adequately connected to breaker box ground. That leaves me with the dilema of:

- grounding coax from the dish via a ground rod at the point of entrance (at the opposite end of the house), presenting another ground loop problem, or

- not grounding coax at the point of entrance, but rather at the wiring closet (30' inside), and grounding to the incoming water pipe.

I'm not sure which would be best. Any thoughts?

Thanks,

Fred

I don't know much about the log type antennas but you may be trying to make it cover a range that is way too much. I wuld think it would be like most other antennas and after about a 3 or 4 to 1 range you would need to do some rescaling of the boom and element diameters.

my apologies. i got "CQ" and "QST" on the same day. the article is in
CQ on page 36 (Jan 2002 issue).

"This difference between liberalism and conservatism
must not be obscured by the fact that in the United
States it is still possible to defend individual
liberty by defending long-established institutions.
To the liberal they are valuable not mainly because
they are long established or because they are
American but because they correspond to the
ideals which he cherishes."

lots of copper is required for high conduction (or J) currents.

don;t forget the other two kinds of currents: displacement (capacitive, or D)
and inductive (or B).

inductive is predominant out to about 1/20 wavelength, capacitive out to
about one tenth wavelength, and conductive currents take over past that.

the original article from the 50's (or earlier) offered that only one 1/4
wave radial is needed. the radial helps establish the "ground" reference for
the image charge.

I have seen commercial LPDs with "feedline" booms where the boom diameters are stepped down as the element diameters step down to maintain a relatively constant electrical diameter.

Where two different diameter tubes join they do not share a common center, but a common side. These common sides then face each other, making the distance between them constant along the length of the boom. So in an approximate way, the center-to-center spacing stays constant as the boom diameter changes along its length.

I hope this is clear.

About once a month, I will put a blurb on here about my Carolina Cyclone series of screwdriver antennas. I hope I don't annoy anyone by doing so, it's just that I get quite good
responses in this manner.

One of the advantages of the Carolina Cyclone is that it is more cost effective while delivering
performance equal to or beyond that of the more expensive ones. Thru careful research and.
with the assistance of a professional plastics supplier, I have found a material that meets all the
requirements of the more expensive competitors in toughness, UV resistance, and power handling. This material is UNMW,or a kind of black Nylon similar or the same as Nyloc used
on locking bolts (the little black or white collar near the head). The material turns well for the
machinist and further reduces the cost because it produces less waste. Delrin is very high cost,
and actually costs FOUR times that of UNMW. Most machinists dread to turn Phenolic because it, too, produces a huge amount of waste, comes off the lathe in long strings of fabric,
and causes a huge mess to be cleaned up when finished. It, too, costs almost 4 times that of
the Nylon derivative. Back to Delrin. What the fellows that use this hugely expensive stuff don't tell you is that, while Delrin IS very tough, UV resistant, and makes great antenna coils,
it is also brittle--meaning that if you prang your coil on a low garage door header, it is more
likely to break. We DO make mistakes sometimes. LOL! Now I do not mean to degrade the
rival materials because they are good antenna coil forms. But the point I AM making is that there is something out there that will do the very same thing at a more reasonable cost.

And that is where the Carolina Cyclone I & II come in.

Cyclone I is a FULL 2" dia
Wire is #14 wound at 8 TPI
Form is UNMW (black Nylon)
Decoupling fingers are a full 1/4" wide for strength, longevity, and tight contact.
Power handling is 800 watts (warranted)
Hardware is aluminum, brass, and stainless steel to resist corrosion and rust.
Coil cover is 1/8" wall LEXAN for a clear weather protection for many years

(Butyl will crack and discolor in a year or so)
Price is just $240 shipped (less whip) to lower 48 States Includes all ferrules, collets, and parts necessary..

Cyclone II is identical to the one above except it is a FULL 3" dia for the absolutely "persnickety" and avid HF mobile DXer. This is for the fellow that wants Texas Bugcatcher
performance and screwdriver convenience. The one who wants "Q" factors in the 400+ range.
Construction is to the same commercial-grade standards and good looks as the Cyclone I.
For example, most "generic" screwdrivers use a wood insert screwed and glued into the bottom
of a PVC reducer. This has very little in the way of threads, will sometimes strip, or come out of the bottom of the coil altogether. Without revealing too much, I have incorporated a 1" long
turnbuckle nut which has the corresponding length of internal threads. It is secured in such a
way that it is almost impossible to, either pull this assembly out of the coil, or to strip the drive
nut. I have repaired some screwdrivers that "mysteriously" stopped travelling, and the cause was that the brass wood insert pulled completely out because there is not enough material in the
PVC bushing to keep it in there securely. Yet, if disassembly is ever needed, each subassembly can be taken apart, repaired with commonly available hardware, and put back together.
Cyclone II handles a FULL 1500 watts SSB! And costs only $350 Shipped to lower 48 states. Compare those prices to some of the big name screwdriver makers! I guarantee performance that will both please and surprise you, or your money back. For those of you who
have never heard of me, I can say that I have shipped Carolina Cyclones all over the US--many to readers of this newsgroup. In 6 years of building, I have had exactly ONE to return for a
mechanical failure, and I swapped it out immediately. You will find no negative remarks on the
internet about trading with me--I do what I say or I make it right. If I didn't, I would be out of
business in short order. But I want to STAY in the antenna business because this is one of the
aspects of ham radio that I love working with.

Earilier, I said that I have a goal. My production is small--anywhere from 2-3 per month except during hamfest season. I don't try for huge numbers because I acquire the parts, I
assemble, I test, and I ship! When you get an antenna from me, it is, indeed, from me! I have
no employees. I work for myself. I need to make that goal of 3-4 antennas during January.
If you are in the market for an HF mobile antenna, please help me make that goal AND receive
an excellent product in return!

Thank you for reading, and thanks to all of you who have purchased the
Carolina Cyclone
in the past.

Happy New Year, and the best of 73 to all,

Jerry

Well, not exactly clear. The tapered feedline booms are interesting.
I haven't seen that in any of the antenna books I have, and the lpcad
program doesn't handle tapered feedlines.

I'm looking at Johnson & Jasik, 2nd Ed, figure 14-24, or the
RSGB VHF/UHF Manual, 4rth Ed, figure 50.
The feedline/booms are positioned one above the other.
The first (highest freq) element left half is attached to the upper
boom, while that element's right half is attached to the lower boom.
This puts the two halves of the dipole quite non-coaxial to each
other. At the back of the array where the elements are relatively
long I suppose this is no biggie, but at the front of the array where
each half of the element is only an inch long they are non-coaxial by
1.7" This seems so warped - I'd think if it worked at all the
polarization would be cocked 45-degrees for the highest freq.
Maybe the elements don't have to attach right on the side of the
feedline, but can dogleg down (or up) and bend out when they reach the

midpoint of the feedline pair? Then they would be coaxial to each other.

If the feed point of the vertical is on the ground, then four won't hack it.
If it is above ground, like a ground plane, then 4 1/4 wave radials are
called for. The FCC recommends AM stations put in 120 in the ground
radials. Amateur ground radials would require somewhat less. I laid down
24 radials around my vertical just below the surface of the ground. Some
put down more.

If the house is only ten years old (then it is still a new house), then it should have an adjacent ground rod AND a connection to the water pipe. You don't have to follow the wires. There would be two bare copper wires exiting the breaker box and one of those bare copper wire clamped to the water pipe. No #6(?) AWG wire clamped to the water pipe; then no bonding for human safety.

Another once noted that electricians cut the eight foot ground rod in half. One ground rod became two for greed and to make it easy to drive that rod into earth. Classic example of an anti-American who worships the business school philosophy - purpose of business is to take a profit - the customer be damned.

You have a new house. It should meet post 1990 grounding requirements. Implied, it does not which is why I would watch for what else is not correctly installed. These are human safety requirements. The house must at least meet minimal requirements for human safety. They existed when the house was built.

To clarify another post, copper water pipes are not sufficient for earth grounding, were never sufficient for transistor safety, and are now no longer sufficient for human safety. For example, a ground to a spigot is an example of absolute irresponsibility. Copper water pipes are bonded to the breaker box for human safety. As noted previously, some jurisdictions now require a bathtub even have its own connection directly to the breaker box - again for human safety. As for transistor safety, we must exceed those earthing requirements. Furthermore no post should confuse bonding of water pipes with surge protection. They are two separate reasons for earthing using same wires.

I have gone to great effort to simplify reasons for grounding. I have defined human safety (as required by the NEC) and transistor safety (there are no national standards for transistor safety). We install the same ground system to address two completely different requirements. A residence is grounded to meet two different requirements - human safety and transistor safety. Analyze the ground system first for human safety. Then repeat the same analysis for transistor safety. If any change is made in the later, then repeat the process over again until the grounding system meets both requirements without modification.

If you worried about resale value, remember you can replace the ham antenna with a good gain cellphone antenna when you sell the vehicle. It might actually
be a selling point if done neatly.

Don't use a hole saw. Two-way shops have a special saw for cutting the NMO mounting hole, much neater and more precise than a standard hole cutter. Dropping the dome light allows easy access to the roof, and for snaking the cable.

Is your clear butyl weather cover on your screwdriver antenna all cracked and yellowed? Can't
find a replacement? I just happen to have the best covers around. They are made of Lexan
and are 1/8" wall thickness! They will remain clear and crack-free for many years. These covers will improve the looks of your screwdriver antenna and protect the "innards" from rain
and snow. They include machined top cap and two end caps (orange) and can be painted to
match your vehicle. Only $16.00 shipped to lower 48 states.

Tnx,

Jerry

As you know, Tom, that's what I do - switch lengths of ladder-line depending on what band I am on in order to feed my system at a current maximum point on the ladder-line. I have verified through measurements that moving the choke to the input of the tuner doesn't protect it from common-mode currents just as you and Roy have said.

Something else that fell out of my measurements is that common-mode current is at a minimum when the system is working into a current maximum point. (25-100 ohms resistive) Common-mode current rises on each side of the current maximum point. That's with no tuner in the circuit and tuning the frequency through resonance. In other words, given the following antenna system, common-mode current is somewhat proportional to SWR and minimum when SWR=1:1.

XMTR---choke======1/2WL ladder-line========resonant 1/2WL dipole

4800. OT: Good Antenna Choice for Off Air Television?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-30 06:05:08 UTC
From: John LeMay <jlemay@nospam.njmc.com>
Message-ID: <pan.2001.12.30.01.08.11.384297.7345@nospam.njmc.com>
Source record: 151953

Hi folks,

Sorry to be a bit off topic, but I hoped a few of you here would have some advice on a decent off air television antenna for VHF/UHF broadcast. I've seen quite a few non Radio Shack branded models that range in price from $90 up to $200.

The antenna should have a good range - 50-75 miles, conditions are good. A few trees but no buildings, etc in the way. Also, it should be able to recieve well from various directions - maybe a 110 degree pattern - since I don't want to install a rotor and try to teach my parents (in their 60's) how to deal with one.

The antenna I want to replace is probably 26 years old and my folks have always had reception problems - white noise, ghosting, etc. I'll also be replacing the 300 ohm twin lead with coax, so any recommendations there would be appreciated as well.

Just so you all don't think I'm an idiot by not just replacing the twin lead with coax before tackling the antenna, I already replaced the twin lead (that was about 20 years old) with some RG59 from Radio Shack a few years ago. Unfortunately, my parent's home was partially destroyed by a fire (fortunately all that was lost was material possesions - you wouldn't believe just how much of that "stuff" I've never missed since). When the antenna was reconnected by the contractor, my father insisted on twin lead since he didn't know anything about it or coax or the differences between the two. Anyhow, while the coax certainly helped reception, there was still a lot to be desired out of the picture.

In case anyone is wondering about location and conditions, my folks are in the Saratoga NY area, about 45 minutes north of either Schenectady or Albany and about a half hour south of Glen Falls. Winter conditions are cold, sometimes windy, ice, and plenty of snow.

If anyone would prefer to reply to me privately, just remove "nospam." from my email address. Thanks for the help!

4802. Counterpoise question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-30 06:45:11 UTC
From: N4LQ <N4LQ@igLou.com>
Message-ID: <3c2eb813_1@news.iglou.com>
Source record: 151955

I have a random length antenna which begins in the shack, goes through the wall and up to the trees. I intend to install a counterpoise, also running it through the wall and outside about 8ft high to some trees and have the following questions.

1. Where should the counterpoise connect? Rig, tuner, ground wire or would outside to the ground rod be ok?
2. When using the counterpoise, should I disconnect my earth ground?
3. Will the earth ground and ac mains ground have any effect on the resonant frequency of the counterpoise?
4. Should I consider these other grounds in calculating the length of the counterpoise?
5. How can I easily measure the resonant frequency of the counterpoise? grid dip etc?
6. Would I be better off using a random length counterpoise and a tuner dedicated to it?

My reason for using a counterpoise is mainly to eliminate rf bites. I'll be using this mostly on 160m and the antenna will be in the form of an 80m horizontal loop with the feedline ends tied together. Any suggestions appreciated.

From: N4LQ <N4LQ@igLou.com>
Message-ID: <3c2eba70_3@news.iglou.com>
Source record: 151956

Not being able to rotate the antenna is a real handicap. The ideal system
for you is a seperate antenna for each channel, aimed in the proper
direction. RG59 coax is very lossy at UHF and should be compensated by a
preamp installed at the antenna.
Here in Louisville, Ky., the local tv shops sell a special antenna cut just
our 4 local channels. I tried one and it really worked. Maybe something like
that is available in your area. 75 miles is a real haul so don't expect too
much unless you can get the antenna up very high for a line of sight path.

Never had a problem with the regular hole saw. The NMO mount
completely covers the little bit of chewing that it does, and a dab of
polyurethane keeps the rust away.

Sorry for the cross post but they appear to be the 2 most appropriate newsgroups for this request.

I am looking at building a Quad for 10mtr, I am looking for a design that someone may have that can be made from fairly easy to get parts.

I would also be interested if it was a 20, 15 & 10 Quad! Same easy to get type of equipment!

I want to build this as a Project for a Scout Group in Australia and then use it at our Jota Station with the view of running an all Year round club and get Youth involved in the great world of Amateur Radio.

Thanks in advance!

That stuff in CQ should have been saved for the April issue.

What a bunch of silly nonsense!

One fellow claims avertical conduit in the ground with a wire in it
makes a "vertical dipole", and the VK6 is nattering on with equally
silly stuff.

CQ needs to edit their materials, or change the name to 73 so we know
what to expect inside.

Hi Jason,

try a quad beam two to five elements (11 units gain if you use five elements)

here is site for plans: http://www.softcom.net/users/kd6dks/quad.html

yes, you can stack them if you want, just watch the phasing cables.

http://www.cebik.com is another great antenna resource.

Hello everyone -

I am looking for recommendations for a good dual band base station
antenna for my IC-706.
Any recommendations other than a discone?

Also any suggestions for distance to space away from the tower for side
mounting?
It will be located about 40 ft up on a Rohn 25.

harold
to be honest with you you might as not waste the time and money
if you cant get an outside antenna for 2 meters SSB you wont hear anything
other than someone close by
6 meters is pretty much the same way uinless the band is wide open
if you have an attic to hide an antenna in i would suggest a 3 ele yagi for 6
meters for SSB and build your self a Jpole for FM work
you could build a Jpole for 2 meter FM as well and it will do well locally but
dont expect to much in range though and also remember that the antennas in the
attic will cause RFI in the TV and phones
good luck

hey bob
if the roof is steel rather than fiberglass you will have a very good ground

as for an antenna a cheap way to go is get a 102 inch whip from radio shack
for under $20 and trim it down to around 54 inches and you have a 1/4 wave
on 6
good luck

The impedance of an end-fed 1/2WL wire is in the thousands of ohms.
You choking impedance needs to be several times that value. IMO,
such a choke/balun at the antenna is just not practical.

However, an end-fed Zepp might work. Feed the 1/2WL wire with
1/4WL of ladder-line and choke the system at the 1/4WL
ladder-line point which is a lower impedance. But note that
the ladder-line will radiate some RF.

>An end-fed Zepp might work.<

If you must use a coaxial feed, try installing a resonant parallel-tuned circuit at the feedpoint end. Connect the 1/2-wave wire off the top (or "hot") end of the tuned circuit. Then, either tap the center conductor of your coax to a 50-ohm point on the L side of the tank or create an appropriate capacitive divider on the C side. Finally, install your common-mode choke (ferrites) on the coax just below the network where they can do some good. This "voltage feed" matching circuit is used by a number of "ground-independent" commercial antennas for VHF service and wire antennas for HF.

I have built 10 meter quads using 1&3/8" oak rod as the boom and drilling it to accept PVC or dowel for the spreader.I was amazed that even unfinished the boom did not warp and only weathered after 2 years.I only meant for it to last 1 weekend (contest) but if I had painted/varnished it I think it would last a decade.I wouldn't use these materials for anything but 6 or 10 m or VHF/UHF.

>CQ needs to edit their materials, or change the name to 73 so we know what to expect inside.<

You are, unfortunately, too correct in pointing that out, Tom. Neither Rich Moseson nor Gail Schieber have significant technical backgrounds--nor does Joe Lynch, the newly appointed editor of a rumored but yet-to-be launched VHF Quarterly (also under the CQ banner).

As the ham market continues to shrink, it is truly difficult to attract competent editors. Fact is, professionals generally like to get paid for being competent. But, are poor market conditions really an acceptable justification for continuing to pump out poorly-edited and misleading technical fare for the ham community? If the goal has become to simply stay afloat, why not shut off the computers, send everyone home, and call it a day? Jim Fiske must be spinning in his grave.

well, i gotta say that, even as a non EE, having seen seen extensive
radial systems built by folks who are true experts in antenna design,
i was 'surprised' at the article. glad to see folks here have the same
kind of questions about it.

That's a mighty tall van -- one of the old 6-meter halos above the roofline
would be good -- short of that, I believe M2 Antennas makes a horizontal loop
for 6 mobile.

Season's Greetings all.

I currently live in a condo setting and have access to an attic with a length of 17', I have though heavily of installing some wire and a autotuner to get on HF (the only other option is putting the TS-120s in my little car and guying up the 7' Outbacker and leaving it there, which was fine on warmer days). And yes I'm still working on my STL, all that's left to do is build the tuning section with remote. I'm still working out the materials and configuration for the drive setup (it won't tune on 40m without an extra capacitor).

The closest HAM supplier (which is in Toronto) doesn't carry the SG products unfortunately (although they are quite aware of them and do think highly of them). The closest they carry for a generic autotuner is an LDG RT-11 (for remote use), a 4:1 balun and a remote control possibly.

The web site is http://www.ldgelectronics.com/rt-11_description.html.

Any thoughts on this unit compared to the SG equivalent would be appreciated.

Thanks in advance!

Hi Pedro,

Assuming that you're using a similar 'Slim Jim' to that I've been using for
almost 20 years,
a SWR of 1.5 measured at the antenna feed point is quite ok.

You should find that due to losses, the SWR presented to the transmitter
will be lower and
therefore the transmitter will output full power.

Remember that SWR is really measuring the feedpoint impedance mismatch,
which in
reality bears very little relation to antenna resonance or radiation
efficiency.

Use subjective testing, and compare this antenna to your previous antenna.

WF3H wrote:
"Since I know many good EE`s who put in miles of radials, makes me wonder---."

An EE`s designs must be effective, economical, and efficient. An engineer seeks the best bargains while solving a problem, in most cases. Many ground wires are used by engineers because it is mandated or because it`s the best bargain. Exceptions to the mandate are allowed, but in most cases, following the mandate is the best bargain.

For broadcasters, G.H. Brown, R.F. Lewis, and J. Epstein researched the questions of how many and how long radials should be. This work was done about 70 years ago at RCA Labs. Salient points of their conclusions are shown by Ed Laport, another RCA Old Timer, in "Radio Antenna Engineering" on page 119.

Ed Laport says that 15 to 150 radials are used at AM broadcast frequencies. Because the radials are a lot more conductive than the soil, current tends to follow the path of least resistance in the radials. The FCC has set a standard of 120 near-surface buried radials, 1/4-wave in length. Ed`s data from Brown, Lewis, and Epstein show why.

A vertical antenna has capacitive coupling to the surrounding earth. A "displacement current" flows between the antenna and earth through the space surrounding the antenna. If this displacement current had to to complete its flow through ordinary soil to the antenna drive point at the antenna base, there would be a lot of soil loss. The radials provide a low-loss path.

If radial wires are mounted over the soil, the problem changes a little. These wires ideally would shield the earth from the electric field. The higher these elevated radials are above the earth, the fewer that are required for an effective shield.

The same G.H. Brown that worked on the best radial wires problem was the developer of the "ground plane" antenna. Brown settled on 4 radials for the VHF vertical mounted many wavelengths above earth.

The info above is from my best recollection. I did look up the Laport pages.

Best regards, Richard Harrison, KB5WZI

From: Joe O <jenjoeo@zianet.com>
Message-ID: <3c2f6ca6.0@oracle.zianet.com>
Source record: 151887

Steve, I would first consider laying many radials on/in the ground. The single counterpoise wire would probably not be very efficient by itself. I use a top loaded 45 ft vertical with several buried radials and four 100 ft tuned elevated radials that are gull wing shaped and about 7 ft above the ground. To tune the elevated radials I connected a MFJ analyzer with a 50 ohm resistor in series with the elevated radials and the buried radials. I added several turns on a 4 inch diameter until I achieved resonance at 1.9 MHz.

Hope to hear you on the Top Band !!

For a single-band half-wave end feed, see the common "j-pole". Not commercial, but you can make it in a few minutes with a piece of LL. Feed it with coax.

In the usual j-pole, the radiator is in-line with the matching section, but this is not required (the radiator can be a horizontal wire with the matching section of LL drooping down at the end).

A 2m version you can look at is at:
http://hamgate.sunyerie.edu/races/antenna/pocket.htm

Do a google search for more info.

I'd go a little further - if a 1/4-wave vertical is elevated 1/2-wave above ground it will work at maximum possible efficiency with only one 1/4-wave (vertical) radial. Very nice omni-directional low-angle stuff too!

no, it actually said that bringing the antenna closer to earth will
increase the feedpoint Z to about 35 ohms. once you get above 1/4 wl,
the impedance is fairly constant at about 20 ohms, according to the
article.

it does say the radials dont act as a 'reflecting screen' and have no
effect on radiation angle or radiation resistance of the antenna.

and thats what's somewhat confusing about the article....

it looks to me like the author is saying there are 2 types of radials for verticals:

1. those radials which replace the 'bottom half' of a vertical dipole and allow the vertical element to be 1/4 wl long. in this case, the radials carry a balanced current, and there is no current flow in the radials.

2. radials designed to reduce earth losses. he says that since these losses occur over tens of wavelengths from the antenna, it's impractical to build a radial system to reduce them:

"In practice, the nature of the earth below the monopole has a very significant effect on its radiation pattern. The major influence on performance comes from the soil conductivity and dielectric constant, out to tens of wavelengths....

In practical terms there is little the user can do to improve the situation since, unless a radial system that extends tens of wavelengths can be constructed, little improvement is possible"

Although I have some background in physics (im a physical chemist), it seems to me most of the earth losses would occur where the field is strongest...at the antenna feedpoint...and that radials would help to

reduce this loss. The article, however, seems to think this idea is
incorrect.

>
>If radial wires are mounted over the soil, the problem changes a little.
>These wires ideally would shield the earth from the electric field. The
>higher these elevated radials are above the earth, the fewer that are

the author says that, since the radials carry a balanced current
(acting as the bottom half of a vertical dipole) they dont screen the
earth at all...

>For those of us who don't subscribe to _CQ_, did it say something like:
>"If the 1/4WL vertical is elevated to 1/2WL above ground, four radials
>are all one needs."? That is a reasonably accurate statement.

What is proposed by the author (Phil Harman, vk6aph), is a 1/4-wave monopole fairly close to the ground (a few inches or feet above the dirt, but not 1/2 wavelength). And the monopole will have two radials suspended just above the dirt. Each radial will be 1/12 to 1/8 wavelength long, and there will be a loading coil in the middle of each radial.

For instance, he has a 1/4-wave vertical for 20 meters with two 60-inch radials, and a common loading inductance of 3 uH. He stresses that the complete system needs to be tuned to resonance by adjusting the coil in each radial.

I dunno if that is something old, something new, or what, but that's more or less the gist of the article.

I don't mean to contradict the sages and historical precedents set by all the ee's that have established norms for verticals over the ages, but...
I had a hillside mounted 40 meter 1/4L vertical in VP2E...cliff overlooking the sea about 80 feet ASL. It wasn't a bad antenna with several radials but as time permitted we (me and my son (VP2EXX) kept adding radials -this was not a one-weekend installation) and made it up to about 60 radials laying on top of the ground...roughly a 30 degree slope on the land facing NW.
If I (we) didn't have a S9+20 (or better) pileup of JAs that I had to work by call area every morning, I'd be checking the connections. US stations didn't stand a chance. That didn't happen with 3 or 4 radials. Local terrain was basically upheaved limestone/sand...there was zero ground conductivity. Didn't grow okra or melons worth a damn either but the peppers, cabbage and 'maters were delicious.

Here we are required to tie apliances to the electrical ground.

>
> Water pipe and breaker box must be bonded. No way around that NEC
> requirement.

NEC requirement and our state and local use Plastic? <:-))

The "Only" ground a normal house has around here (central Michigan) is a
ground rod at the service entrance and the one at the pole.

I'm not arguing the point that it may be an NEC requirement, but the state
of Michigan sure doesn't use it.

Hi Cecil,

Probably easier to separate four radials' tips from a mast
(electrically and physically) than for the single lower half of the
dipole (where there would be an insulation/isolation barrier that the
feed would have to go through and up inside the lower half.

There is current flow, the individual contributions of each radial to
the antenna's pattern are canceled such that the vertical element
remains the odd man out to dominate the pattern.

>
>2. radials designed to reduce earth losses. he says that since these
>losses occur over tens of wavelengths from the antenna, it's
>impractical to build a radial system to reduce them:

Radials have nothing to do with earth losses out to 10 wavelengths
much less a 10th of that. Certainly up close, but only to the degree
of coverage (more radials - less loss).

>
>"In practice, the nature of the earth below the monopole has a very

Actually it is not "out TO tens of wavelengths," but rather out AT ten
wavelengths. At this extreme we find what DX angles may be supported
by the characteristics of far ground. Near ground more impacts the Z
of the antenna, we can fairly take it for granted that the radiation
pattern is not going to vary greatly.
>
>In practical terms there is little the user can do to improve the
>situation since, unless a radial system that extends tens of
>wavelengths can be constructed, little improvement is possible"
>
Little improvement in low angles of radiation that is (less than 20
degrees), unless the far ground is treated as well as the near ground
(the frustration is already being expressed accurately).

>Although I have some background in physics (im a physical chemist), it
>seems to me most of the earth losses would occur where the field is

>>
>>If radial wires are mounted over the soil, the problem changes a little.
>>These wires ideally would shield the earth from the electric field. The
>>higher these elevated radials are above the earth, the fewer that are
>>required for an effective shield.

More nonsense, the distance is the key contributor to lowering loss,
the ground sees the same signal but at a lower intensity when
everything is raised. Local ground has become remoter and the
antenna's Z follows accordingly. Any benefit to DX angles arrives as
a product of raising the antenna, not any monkey business with radials
(even one).

Bob, WF3H wrote:
"---it seems to me most of the earth losses would occur where the field is the strongest...at the antenna feedpoint...and that radials would help to reduce this loss."

The article may imply something else, but the old experts agree with Bob.

Capacitance is proportional to the area of the plates and inversely proportional to the spacing between them. The earth is a large plate but the distance between the plates of this capacitor the vertical antenna makes with the earth grows with the distance from the antenna. So, capacitance to the earth falls with the distance from the antenna. Thus, the displacement current is greatest near the antenna.

The article may say radials carry balanced current. That means the azimuths may be nearly balanced in the currents they carry. But, all azimuths are carrying currents which at the instant are flowing in the same phase either toward or away from the vertical antenna. Their sum is equal to the current in the vertical antenna. Their influence at a distance should just about balance out to produce a uniform effect at all azimuths.

The current flow in an elevated radial induces current in the earth below. The induced amplitude depends on proximity, imbalance in the influence of the various radials affecting the induced current, and the strength of the radial currents themselves.

So, even if radials capture all the electric flux from the vertical, the earth still is excited by nearby radials. I may have overstated the case for screening the earth from displacement current. The extent of this screening is incomplete at low radial altitudes. At high altitudes, screening improves even when the number of radials is reduced.

Radials reduce losses when they are only a fraction of a wavelength because the cross-section of earth engaged in carrying the signal grows large at the far end of the radial. It`s just geometry. It`s the large area which produces high conductance and high capacitance in the soil. Though the characteristics of the soil may be unchanged, there is a lot more of it "in parallel" far from the antenna. That is why radials don`t have to be infinitely long to do a good job. In many situations, you would do as well with twice as many radials of half the prescribed length.

Best regards, Richard Harrison, KB5WZI

We had ground-plane VHF and UHF antennas as well as dipoles. The dipoles were at the outer end of the yardarms, and mounted vertically. The ground plane antennas could be mounted inboard. That was quite a while back, bit I remember that much.

Anyone ever use the scantenna or the like form atennawarehouse.com
Its a wide band antenna which I plan to use for a PCR-1000 from Icom.
How high should I place it for a plain/prairie area like Houston area. I
live in a rural area, no tall buildings or such..

>For those of us who don't subscribe to _CQ_, did it say something like:
>"If the 1/4WL vertical is elevated to 1/2WL above ground, four radials
>are all one needs."? That is a reasonably accurate statement.

the article said a 1/4 wl piece of vertical wire inside an insulating
conduit can be used to form a "perfect" image or counterpoise.

To improve that "perfect ground" (if it really is perfect why add
anything?), he added four radials under **fresh** water!

Since fresh water has lower conductivity than moderately poor soils, I
have no idea how that would improve a perfect ground.

In another article, another author suggests a SHORT four wire radial
system with loading coils is better than a full size system...even one
with many radials.

He probably got that idea from a flawed article in Communications
Quarterly, where conclusions were reached based on only having equal
currents in each wire. Somehow these people think equal currents in
each wire means a radial system with four wires won't radiate and
couple to earth very near the wires.

They obviously never have owned or used FS meters, or even had a
florescent lamp below those alledged non-radiating radials.

By the way, both claim good experience and results on 160 meters. One
is a VK6, but with over 100 different VK's in my log on 160 his call
does not show up! I have logged thousands of contacts with VK's on
160, some using mobile antennas and some using very low power and
marginal antennas (like 5watts to ten foot high antennas). yet no
where in all those contacts have I worked the person who claims near
100% efficiency with four short coil loaded radials.

It seems odd the people without exceptional signals, or without any
signal at all in some cases, are those who know how to build magic
100% efficient antennas.

Source record: 151917

I am wanting to scale the 22 element yagi design found in the ARRL handbook for UHF TV channel 43 (647 mhz). Some modifications are required for a 75 ohm match. I have used the NEC 2 (numeric electric code) program to predict the gain, impedance and antenna pattern. So far I am able to predict 17.5 dbi gain, need about 20+ dbi gain. Probably need a longer boom. Any one have experience with the NEC program ?

Any suggestions or comments are greatly appreciated.

Robert.

Bob, WF3H wrote:
"---according to the article, it seems 2 (radials) would be fine..."

Suppose we have a 1/4-wave vertical driven against a 1/2-wave horizontal wire at its center to serve as a pair of 1/4-wave radials.

There is a problem I see with this as a ground plane and it is non-omni propagation. If this antenna were elevated, but not too high from ground, the radial tips which are open-circuit would have an enhanced capacitive effect to earth. The resulting large displacement currents from the tips would make a broadside vertically polarized array which would deform the uniform azimuth characteristic of the classic ground plane antenna.

Brown probably tried this idea in his experimentation. If I recall, he tested his antenna ideas in the lab on a very small scale over a near perfectly conducting sheet. The 4-radial ground plane proved best by test.

Best regards, Richard Harrison, KB5WZI

Cecil is right Rick.

Those who "think" a choke isolator is effective for making the shield
become the other half of an 'end-fed dipole" are having some sort of
wild antenna fantasy. They have not bothered to look at impedance
limits.

While a parallel resonant circuit would work on one narrow range of
frequencies near resonance, the components would have to be very good
even at modest amounts of power. It would be much more simple to just
feed the thing the normal way, or to make a decoupling cage that
skirts the wire (although it would likely have to have an additional
choke).

I'm afraid this is another one of those things that slips by everyone
because no one bothers to consider how the system really works, or
make any measurements.

Robert,
I don't use that program, but the open I do have uses
the same basic 'engine', so should produce the same results.
Which is irrelevant to the question. Doubling the boom length
should produce more gain. If it isn't enough, add a few more
elements. Still not enough gain? Stack a couple of them.
There are all kinds of possibilities.

Interesting variations.
Our, newly installed, gas pipes are metal; but the buried pipes feeding
the street and our house are all plastic.

However, our cablevision is grounded to the water pipe and at the point
of connection to the water pipe the installer made a simple air wound
inductor - 7 turns of about 1" dia. I have noticed a similar
configuration on all of the power poles in our area where any connection
is made to the pole ground wire.

I am curious as to the purpose of these inductors. What effect might
they have on a rapidly rising pulse as from a lightning strike?

Doc,

That's true, but when I first built a DK3 type screwdriver, I went
everywhere trying to find
a Butyl tube just the right size. Around here, the candy never comes in
exactly the same kind
of tubing every year. It may be round one year, square the next, or too
small, or too big.
And there's no guarantee that this flimsy stuff will even LAST a year. Some
people will come
up to your vehicle looking at the "funny" antenna and squeeze the cover and
CRACK! The
cover is now ruined. Yes, I have seen it happen. With the Lexan, it is
doubtful that someone would squeeze it hard enough to break it--unless they
whacked it with a tire iron, it will be there
year after year, after year, after year..... Why not get a good
cover and be done with it? Besides, my covers are diet "friendly" and won't
cause you to gain weight. Now candy CAN be added, but that costs extra.
LOL!

The diskcone is easily assembled with no cutting, or other work, other than
merely screwing some connectors together. I used one and it worked just
fine.

As to omni directional and gain. Gain is merely taking signal from one
place and adding to to that from another. In the case of the colinear, the
gain comes from above and below the plane that is perpendicular to the axis
of the radiator.

It's not the narrow band part that gives it the gain, but the multiple
"resonant" elements.

Thanks for your reply Doc,

My main concern is that if I relay on the NEC program, to achieve my objective, the actual result might not agree with the calculated results, assuming that the antenna is built with sufficient precision. How reliable is the NEC program ? The NEC program that I refer to is the N2D1100.exe found on several websites. For larger antennas there is NEC2D250.exe . It appears that these programs were originally programmed in Fortran and later modified and compiled for the MS-DOS platform. I assume that all the versions work the same, except for antenna array size considerations, and can be referred to as the NEC version 2 program.

Just to add one more object; the antenna must be as directive as possible. I am trying to receive WNJT-DT a PBS digital station from Trenton, NJ. WNJT-DT is 40 miles and behind a 600 foot hill from my location. Razor sharp antenna directivity I believe will help to minimize ghosting.

Again thanks,

Robert

The impedance is zero at the end of a folded dipole, since it is now a
half wave shorted feed line. The antenna currents are not unbalanced,
since a j-pole works just fine. Look a the current distribution, a
point is a point, no matter if centered or not.

Correct as usual, King Friday. And, I also agree with you that the idea of placing ferrites at a current node to "break" a current path isn't a judicial application (something I don't believe I advocated, but something I've seen recommended in print in several places).

>It would be much more simple to just
feed the thing...<

Especially if you want multiband operation. Or, you could do what I did in 1957 as a Novice--bring the end of the 1/2-wave wire into the shack and connected it to the pi-network (took forever for my fingers to heal).

Not trying to be contrary and I do believe the bigger antennas are the way to go, but... I've used "on the glass" antennas for years out of necessity and with very good results. Compared to a half wave I could tell no difference and a slight difference with the 5/8 ths wave. And..yes, I could notice a difference when well out away from the repeater, but I could reliably work the thing out about 25 miles. With the colinear up "on top" I end up with a 5' antenna on top of a 6' SUV. Now that does make a difference as to how far out I can work the repeaters, but very little difference within 25 miles.

However, after having shortened my Trans Am by about a foot and a half (took a GMC Jimmy broadside at 50 MPH and put the firewall up against the bottom of the dash), I now drive a 4-runner with a large mag mount on top which is holding one of the Diamond colinear verticals. I no longer need that "on the glass" on the hatchback.
BTW, the impact was great enough that the mount for the remote head on my 700D folded flat on the dash and I don't mean at the hinge.

To be fair I did find a couple of the "on the glass" that weren't worth the time it took to stick them on and they came with self stick adhesive tape.

> If you live close to lots of repeaters, it might be OK. IF you are out in

> small screws. No-

I've found that most of these antennas work far better when centered on a good metallic surface and as high as possible. On the TA, it was the higher the better and the roof was not an option as it was plastic. Near the top of the window in the hatchback worked quite well.

> one is going to see these holes, and they can be repaired with JB Weld
when

Now there is a good location.
My mag mount raises the bottom of the radiator level with, or a tad above
the level of the rack.

> Cherokee, you might consider a mirror bracket attached to one of the
rack's
> bars with longer

Either Diamond, or Comet (one or the other..maybe both) makes a very nice
mount that will clamp to the cross bars and uses a tiny high quality coax
that will make it to the interior before going to the larger coax.

BTW, the larger colinears have a "lift and fold" feature.

You just have to remember to "lift and fold" BEFORE going into the garage.

Sorry, I completely missed the "folded" part. What I said applies to
a dipole, not a folded dipole. A folded off center fed dipole's feedpoint
impedance decreases as the ends are approached.

> The antenna currents are not unbalanced,
> since a j-pole works just fine. Look a the current distribution, a
> point is a point, no matter if centered or not.

That a J-pole "works fine" doesn't mean the currents are balanced.
Although both sides have high impedances, the short side of a J-pole
has a higher impedance than the long side.

There is a bit more to it than that as you are allowed to go "I believe" 20
feet" above the trees. "Unless you are off the end of a runway", where no
one in there right mind would build.

Also there is a clear zone off the end of the runways which varies with the
length of the runway as well. I think it uses the formulas you listed above
and nothing may be put within the area where the height is 40 feet or less.
It may be 60 feet. I think the clear area spreads at 3 or four degrees as
well.

Now, I'm gonna have to get the AIM out and read.
When I find it we'll see how close I was.

I'd have to look the distances up, but the glide slope is normally 3 degrees
and you may not stick anything near that.

On occasion I have missed TV antennas that someone had just gone ahead and
put up, by less than 20 feet.

We had a new subdivision built right across the expressway from the airport.
I had taken off on that runway on hot days, loaded to gross and cleared the
houses on the other side by only a slight margin. They were complaining
that the dishes in the cupboards were rattling and they couldn't talk to
each other when I went over.

Or use a pipe mounted on the rear bumper that will raise the base of the antenna at least even with the top, if not above. It'll need to be sturdy as that is one whale of a lot of leverage at expressway speeds.

4888. Re: Water in coax

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-31 05:07:02 UTC
From: Roger Halstead <rdhalste@tm.net>
Message-ID: <WnSX7.938$9d.169939@newshog.newsread.com>
Source record: 151840

I think that water proofing connectors is no longer the great trial that it once was.

Go down to the local hardware, or marine store and pick up a can or two of liquid electrical tape. I use it in both black and red. Smells to high heaven, but that stuff really works. I use Dow Corning, DC4 or DC5 compound to flood the "upper" connector. Just use enough to be sufficient. Don't over do it. (This is what it was made for- Actually sealed the spark plugs on B-17s in WW-II) Don't get any on the outside of the connector or coax.

I then paint the outside of the connector and coax with the liquid electrical tape. I usually use 3 coats and let it dry thoroughly between coats. This stuff was designed for a salt water marine environment.

I don't even bother with vinyl tape.

Of course there is another "thorough" way to seal the connectors.
Go to an electrical supply house and pick up a length of 3-M flooded, heat shrink tubing. Unshrunk it is about an inch inside diameter . It will slide right over a PL-259 if you forget to put it on first. The inside is coated with something akin to what's used in a hot glue gun. You cut a piece about 3 inches longer than the space taken up by the connectors. That gives about an inch and a half down over the coax. Everything gets glued together and sealed. It makes a very good water proof connection and it's a good mechanical connection as well.

A 4' length of the large flooded heatshrink tube runs roughly $10 and is long enough to make a lot of connections.

IF I can get to the splice, I always use the flooded heat shrink, otherwise it's the liquid electrical tape...Unless the weather is bad and then it's the old coax seal and tape. Unfortunately the last time I was up the tower it was too cold for the good vinyl tape to stick to itself, let alone anything else.

That's interesting! How do you have maximum voltage and minimum
current at that point (the ends) with zero impedance?

From _and part of which I was_, George Brown's autobiography:

". . .In our initial experiments we found that only two horizontal rods (ground rods) functioned just as well as four. Many people from the Broadcast Sales organization came by to view our tests and they always expressed doubts as to the ability to radiate uniformly when only two ground rods were used. To quiet them, we used four ground rods for a while, thus stilling the criticism. When the antenna became really popular, we did not dare confess to our ruse.

"Months later, New York City ordered two ground-plane antennas for use on harbor fireboats. Their representative worried that the ground rods would not always clear obstructions on either side of the boat. I promised to work out an arrangement to overcome this objection and this we did by simply using two ground rods which ran fore and aft on the boat."

Robert,
You have to remember that all the 'NEC' based modeling
programs are 'isotropic' in nature, not 'real-world'. If
you 'plug' in enough information about the environment, it
will give you a more realistic output. But, not many people
are going to go to that much trouble. (How much does a tree
affect the antenna? I don't know, and I'm not going to go to
the trouble to find out.) To get a very realistic 'real-world'
output from any of the 'NEC' programs you'd have to have the
computing power of something like a 'Cray'. My computer isn't
even close to that (LOL)! The modeling programs are good at
what they do, which is to give you an approximation of what
a particular antenna 'acts' like. In the end, you still have
to get out there with a field strength meter and take readings.
But instead of millions of readings, you only need to several
hundred (LOL).
As to your situation, the 'best' option is height, but
that's probably not too practical. Good luck...
'Doc

Hi Doc,

Hard to say what a "Cray" is. Back when I first heard of it:
>The first Cray-1ï¿½ system was installed at Los Alamos National
>Laboratory in 1976 for $8.8 million. It boasted a world-record
>speed of 160 million floating-point operations per second
>(160 megaflops) and an 8 megabyte (1 million word) main memory.

My machine runs along at 1000 MIPs with 512 megabytes main memory.
It also beats the Cray-2, and perhaps the Cray Y-MP (about a dozen
years old).

Today's $1000 system has more computational power than the entire
Pentagon during Vietnam, or just enough to play B&W episodes of "The
Beverly Hillbillies" in streaming video on demand. What a country!

It's nearly impossible to put a number on the accuracy of a modeling program except for specific models of specific test antennas. In general, NEC-2 is very good at modeling Yagis, but with a few caveats. One is that if the elements aren't constant diameter (i.e., if they're made of telescoping tubing), NEC-2 will be considerably off. Commercial NEC-2 based programs like EZNEC substitute a constant-diameter equivalent element in order to achieve good results, but NEC-2 doesn't have this capability. Another thing to consider is the capacitive effect of a metallic boom. The modeling programs don't automatically consider this, and adding a boom to the model makes no difference in the result. I'm not an expert at this, but I recommend Leeson's _Physical Design of Yagi Antennas_ (ARRL) for more information. You might also find something on L.B. Cebik's web site, http://www.cebik.com.

In general, inaccuracies will affect the nulls much more than the forward pattern. I've had quite a few people tell me of successfully modeling Yagis of 15 or so elements with EZNEC, and I'm sure some of these, who were government customers, made actual measurements to confirm the results. But for anything as sharply tuned and sensitive as a long Yagi, I wouldn't guarantee precisely accurate results even so.

Of course you realize that the gain and directivity of a Yagi are inextricably linked. Once you specify one, you're stuck with the other.

I can't find the plans now, I did have them bookmarked,
and the website told you everything you needed to build
the loops. But- like you're finding out, they're not
necessarily for base station use. In mobile use, however,
that's the best thing going. Do a search on the 'net for
"build a loop antenna" and you'll probably get back a
couple of the sites I found. Make sure the search request
is in quotation marks, or you'll get back a bunch of junk.

well said, OM!
Download program ENDFEED.exe from website Http://www.g4fgq.com and
make some successive parameter change to see how impedance varies over
frequencies and wirelength as well as height and other, the program
also shows calculated system and element efficiency

==========

Very true Richard.

It is interesting to look at the same 'problem' from another aspect.
Consider a buried radial wire to be a very lossy transmission line with a loss of the order of 40 dB per wavelength.

Such a wire also has a very low propagation velocity, VF = 0.25 down to 0.1 depending on soil permittivity and moisture content.

So the physical length of a 1/4-wave of buried wire is a small fraction of the free-space value. Not that a 1/4-wavelength has any special significance because attenuation is high enough to suppress resonant effects.

There's little to be gained by lengthening a buried radial wire beyond, say, 1/10th or 1/20th of a free-space wavelength when there's hardly any current current flowing in it at that distance from the focal point. If you have more wire to bury then bury it where it can be more useful - increase the number of short radials. And it will be OK to stop long before reaching Marzipan's magic number of 120.

By the way, a wire just lying on the soil surface has a propagation velocity about half of the free space value. However loss is only of the order of, say, 10 dB per wavelength, again depending on soil characteristics. Weakened resonant effects will be present and the optimum length of radials is crudely 1/8 of the free-space wavelength.

Roy Lewallen wrote:
"George Brown`s autobiography:
In our initial experiments we found that only two horizontal rods
(ground rods) functioned just as well as four.----."

I won`t argue with the record and the tests. My ground planes have always used four radials as dictated it seems by the RCA sales department. I`ve already explained my logic, flawed as it must be.

This is an example of why logical designs need real proof from experimentation.

A third step is required too. That`s to put the idea into the hands of a number of end users so that they can commit the unimaginable with it.

Some day I hope to read George Brown`s autobiography. I should say I was not quoting Ed Laport on the ground plane. Now, I can see why he was nearly silent on the topic.

I appreciate Roy Lewallen`s input.

Best regards, Richard Harrison, KB5WZI

I'm not sure why the installer installed the inductor before a
connection to the water pipe. Normally, you would create a large
inductor in the signal bearing cable (NOT the ground connection) where
it enters the building, while keeping ground connections short and
direct. The reasoning is that lightning has a substantial AC
component. In actuality current flows in one direction, then
reverses, then reverses again, etc. Placing inductance in the path
creates reactance which is essentially resistance. Current from the
strike would therefore take the path of least resistance and be
shunted directly to ground.

We normally do this with transmission lines going to a tower. We keep
the ground connections LARGE, short, and direct. In fact, we use
copper strap or braid to make connections, while transmission lines
have a few coils on the outside of the building where it is practical
to do that.

I'd say w_tom's advice is excellent.

Good point and nicely said. Lambda = V/F. The wavelwength is smaller when the velocity is smaller.

There is no point extending the road when all the traffic has played out.

Brown, Lewis, and Epstein did excellent work with radials. Their RCA colleague, Ed Laport, has a nice summary of some of it on page 119 of "Radio Antenna Engineering".

Are you sure that he didn't just intend to leave a little extra wire,
in case the ground point had to be moved for whatever reason?

It may not be an inductor, just a coil of extra wire.

For a whole whopping 1/2 S-point more gain the larger yagi's only good point is its nulls and F/B ratio to put some noise in.

I agree that the 3-el yagi is a well known design and will work as advertised using any of the large number of mechanical and matching designs out there, where as the horizontal loop is pretty uncommon in the books.

I'd build the loop though, it is much smaller physically which I can use in my limited space and I like fooling with 'exotic' designs, even if I shoot myself in the foot a few times, it is all the more fun that way.

A quad might be a good compromise.

Go to zonelabs.com and download ZoneAlarm. It is a software firewall that will keep others from hacking into your pc.

If your work is that important, then keep it on a seperate PC that is not connected to the net, or to the first PC.

You might also check out Gibson Research Corp site, grc.com (I think). He has lots of good info on firewalls, how they work, etc, and even a way to test your security.

My 19th edition ARRL Antenna Book describes an HF discone antenna with a 40 foot A-frame wood mast as the center point. The article gives theory and detailed construction info. The chapter also references QST, July 1975 for an HF discone article by J.S. Belrose.

Do an Internet search on "DL6WU", and you should find a DOS program
that designs long Yagis by formula. It includes boom corrections.

What's the general rule of thumb for VHF/UHF antennas that don't require a ground plane? I know that you need a ground plane for the typical 1/4 wave and you don't need anything for a 1/2 wave. But, what about all the other antennas? I want to mount an antenna up high on my soft top Jeep and don't want to have to rely on a mount for the ground plane connection (not interested in through-glass installations either).
1/4wl, 1/2wl, 5/8wl and other multiple wavelength antennas like the one's Diamond advertises?

Drink,
If you mount the antenna (no matter it's electrical length)
to
the body of your Jeep, you ~will~ have a groundplane...The body
of
the vehicle. If you use the windshield frame, for example, the
frame becomes the groundplane. If you use an extension of some
kind
and mount to the tire carrier, or bumper, the extension (if it's
metal) becomes the ground plain (actually a vertical counterpoise
which does the same thing).

Message-ID: <3C30B738.2F2F7E9A@grove.iup.edu>
Source record: 151868

I've been off of work since December 21st and I have been playing with NEC-2 non stop. I have really been thinking about the accuracy's and how useful is it really to spend hours and hours using a computer to study antennas.

You look at Bob Haviland's book, "The Quad Antenna", the whole study seems to be based on hours of time using MININEC. I was particularly struck by his statement that a feeding a loop through the spreaders netted a gain of nearly 1dB over a standard feed.system. Without even touching the computer, I built a full scale model for 28Mhz. Gain seemed to match the standard 2 element. However, F/B and F/S ratios were very very poor. This was compared to a standard 2 element, built on the same framework.

So, I modeled. To my surprise, the feedpoint impedance reported by NEC-2 matched my real life model almost exactly. The overall 2:1 bandwidth was a little narrower that it actually occurred, but I was still impressed. Then, looking that the patterns produced by NEC-2, I found clean patterns with normal F/B and F/S ratios, almost matching that of a standard 2 element. NEC-2 didn't indicate any gain increase over the standard 2 element (no matter what lengths I tried).

So, I sit here, wondering what I've gained by modeling by computer. Everybody is on the computer modeling bandwagon, antenna manufactures must state "computer optimized", lots of work based on computer study.....but it all comes down to Orr's methods in the real world.

Scott.

Within the last year, there were two articles in 73 about setting up a folded dipole "city clothseline style" and feeding it with coax, then just pull the feed around until you got a good match!

If you are using Ladder line to a tuner, just cut the dipole to fit, keeping
the sides equal. Mine is 90 feet long, between trees at 100 feet.

I got ya there, Doc. I'd like to mount it to the middle of a light bar, above the windshield frame. I'm just asking because a Diamond antenna ad showed several antennas of 1/2l, 5/8l and multiple electrical lengths that said a ground wasn't necessary unless specified (only 1 or 2 actually needed it). What I want to know is, with those antennas that, "don't need a ground", how much affect's added by having a good ground? Sure, a good ground will improve an antenna's radiation/reception. But, are they saying that the difference wouldn't even be noticeable (and is that a false claim)?

4922. Re: radials and vertical antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-12-31 20:10:47 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C30C647.14DEAC10@eznec.com>
Source record: 151775

The only problem with this simplified analysis is that can produce conclusions that don't agree with experimental measurements. At least one problem is that it doesn't account for the considerable coupling among radials that takes place. It does, however, reach the right conclusion if there aren't a large number of radials.

Brown, Lewis, and Epstein showed measurements of radial currents in their 1937 paper. While the current drops fairly rapidly when there aren't many radials, the measurement of current with 113 radials (the largest number they used, because they ran out of wire) shows the following: The current is very nearly constant out to a distance of about 0.125 wavelength (all values are in free-space wavelengths), then drops to about 60% at 0.25 wavelength, rises again to about 85% at 0.32 wavelength, drops again to about 65% at 0.375 wavelength. So there's very significant current flowing at a distance of around 0.4 free-space wavelength when a large number of radials are used. With 60 radials, the current hits a minimum of about 25% at about 0.23 wavelength, then rises to about 35% at 0.375 wavelength, then drops again. These are from their Fig. 42 on p. 781. NEC-4, which is able to model buried conductors, gives results reasonably similar to Brown, Lewis, and Epstein's for field strength and impedance, and shows a similar current distribution along the radials.

A simplified, but reasonably accurate, summary of Brown, Lewis, and Epstein's conclusions is that if the radials are short, adding more radials doesn't help a whole lot. And if there are only a few radials, making them longer doesn't help a whole lot.

In practice, it's seldom useful for an amateur installation to have a large number of radials. While a few percent additional coverage area, and stabilized feedpoint impedance, are important and very worthwhile to broadcasters (who don't base their radial system designs on old wives' tales, but on sound economics), the difference in field strength is generally negligible for long range communications.

I am new to radio/TV reception and i use a 'flying saucer' antenna for TV reception. But in the tropical country i live in we get heavy rains with lightning and thunder and it is quite common to get TV's burnt up because of that.

The precaution i take is to disconnect the antenna from the TV each time such conditions are present. But i am looking for the best way to protect the antenna from such weather conditions and also much of the time i am not at home so i cannot disconnect the antenna and the TV may blow up anytime.

Thanks for helping me out :)

Regards,

RayOfLight

>Is there a commercial one available that is less than about 100
>feet? Or is there some way I could shorten it without traps?
>
Two options - you can use 'em both:

When feeding a dipole with ladder line, its exact length is not extremely critical. If your "flat top" is at least 110 feet you will not be able to tell the difference from a half-wave on 80. When you get below 100 feet the efficiency begins to suffer noticeably on 80.

The ends of a horizontal dipole can be allowed to hang down vertically in order to fit it in spaces that are a little too close together. The main thing is to maintain symmetry and don't let the ends too near the ground.

Example: Suppose you have two tall trees 100 feet apart, and you can get ropes up into them 50 feet up. Make up a 130 foot dipole with insulators at the ends, middle, and 20 feet in from each end. Hang the dipole by the "20 feet from each end" insulators, and secure the end insulators with additional ropes so they hang vertically. End result is like this, going from one end to the other:

- 20 foot vertical section a few feet away from tree - end is 30 feet off the ground.
- 90 foot flat top fed in the center with ladder line
- 20 foot vertical section a few feet away from tree - end is 30 feet off the ground.

Total dipole is 130 feet long but the "flat top" is only 90 feet long.

Source record: 151780

As I recall, feeding a half-wave (or odd multiple thereof) with a parallel-resonant circuit results is what at one time was known as the Fuchs Antenna. Seems that all antennas must have a name, or they don't work! <:}

In the late 40's I used a 260 ft wire end-fed with a tuned circuit inside the shack by the window where the wire came in. The tank coil was center-link coupled to the "swinging link" on the final amp tank coil. The other end of the coil was floating.

I would tune the circuit for maximum brilliance of a 40 watt fluorescent lamp tied on the far end of the antenna. That worked well at night. For daytime tuning - remember now that I was just a teenager! - I would tune for maximum arcs drawn with a wooden/lead pencil off the other end of the coil. The transmitter tank was resonated using a 250-watt incandescent lamp as a dummy load and then left alone with all further tuning being done at the antenna tuner circuit and loading adjusted with the swinging link. Real high-tech stuff for around 1947!

This antenna worked well on 80 - 20 meters and was especially effective on 20 DX, even though fairly low to the ground.

Many antenna configurations have evolved over the years that amount to a parallel-tuned circuit feeding one end of a half-wave, or longer, antenna. Fuchs must have know what he was doing, but probably not what he was starting.

I recall reading that when Brown developed his "ground-plane" vertical, he
also found that a single radial was adequate when the antenna mounted well
above ground. When the antenna was mounted lower, he found that two radials
would compensate for the lack of added height.

Finally, he elected to use four radials for symmetry and to offset comments
that "two radials obviously aren't enough!"

> I can't quite fit a 80/40 120 foot dipole. (450 ohm Ladder line)
==========
Dear radio amateur friend,

It would seem you have been hoodwinked by antenna manufacturers and their waffling, plagiarist, old wives, baffle-gabbing salesmen, and newsgroup do-gooders, into believing that the actual length of a centre-fed dipole antenna is of vital importance.

It is in fact of little importance provided it is longer that about 1/3-wavelength at the lowest frequency it is wished to operate and the feedline impedance Zo is a few hundred ohms or more. A Zo of 450 to 600 ohms is ideal.

So prune the length of your dipole to fit into your back yard. But better still, bend down at the dipole ends the excess length towards the ground to leave the overall dipole length unchanged. Or you could bend the excess length sideways or upwards. It makes little difference whatever you do.

You could consider increasing the overall length by having even longer ends hanging down. At the lower frequencies, 160m, 80m, etc an increase in overall length by this method may be beneficial. It is a case of seeing what happens in YOUR particular back yard. Backyards are all different from each other.

So bend downwards or cut off the ends of your dipole until it fits into the space available. The only difference you might notice could be the relatively small changes in the settings of your antenna tuner situated at the transmitter output.

The fellow at the other end of the QSO (or contest contact) will not notice any difference even it is possible to do an A/B test.

Go ahead, erect your dipole of any sensible length and I wish you all the very best of DX in 2002, 2003, 2004 etc. ;o)

At resonance, the feedpoint impedance remains resistive and increases. When the feedpoint is moved from the 0.5 to 0.333, the impedance increases by a factor of about 3.8 (nearly four). At the very end, the impedance is quite high, about 50 times the centerpoint impedance.

Two other noteworthy things occur, as well. The performance at harmonics changes radically. A center-fed dipole (regular and folded) shows its fundamental impedance at the fundamental & at odd harmonics (making the usual small correction for end effects at the harmonics). At even harmonics, it shows a high impedance. This neat rule goes out the window when you feed off-center. In fact, a published antenna in the early 1950s was an 80-meter piece of wire (non-folded dipole) fed at 0.333 of its length with 300-ohm twinlead. This was a fair match to the transmission line at ALL the harmonics of its fundemental, enabling operation on 80, 40, 20, 15, & 10 meters with one antenna. (Today, it sould also be a tunable match on 30, 17, & 12 meters, and would IHMO, be a better "all-band-when-tuned" antenna than the Windom or any of its variants.)

But the other thing that goes out the window with center-feeding lost is all-frequency voltage balance. In a center-fed dipole, the voltage midpoint of the two transmission line conductors is zero; if you fed that transmission line with a winding on an ideal transformer, the centertap on that winding would be at zero volts with respect to ground, and a wire between said centertap & ground would carry no RF current. This state of balance is LOST when feeding off-center & off-resonance. The usual "balun" inside a mass-market antenna tuner (really a 4:1 impedance-ratio autotransformer with the centertap permenantly grounded) will NOT do what needs to be done. You will end up with all kinds of RF on the station ground wire, with the corollary large unbalance in transmission line currents. Even a "true balanced" tuner like the a Viking Matchbox won't work, because it effectively has a grounded centertap on the antenna coil. What you would need is not a Balanced Output, but a true Floating Output. Back when off-center feeding was being used, most transmitters had link coupling, so the output really did float, and the thing worked as well as any other dipole. Today, you are going to have problems. Probably the best approach would be a large-as-you-can-make-it common mode

choke on the tuner input, with a rejiggering of the tuner to disconnect everything on the antenna side of this "choke balun" from tuner case ground.

Not necessarily so. There was a technical exchange on this topic in QST in 1954 (my references are at at work, I'm on holiday). The problem is not that off-center feed causes feedline current imbalance, but that it abandons voltage balance, so currents become unbalanced if your source has a ground connection that tries to "reassert" a voltage balance different from the antenna's.

Excellent advice Reg. If he follows it he'll have a lot of fun on the
air.
